Notes for Recitation 6

1 The Pulverizer

We saw in lecture that the greatest common divisor (GCD) of two numbers can be written as a linear combination of them. That is, no matter which pair of integers \( a \) and \( b \) we are given, there is always a pair of integer coefficients \( s \) and \( t \) such that

\[
\gcd(a, b) = sa + tb.
\]

However, the proof was nonconstructive: it didn’t suggest a way for finding such \( s \) and \( t \). That job is tackled by a mathematical tool that dates to sixth-century India, where it was called kuttak, which means “The Pulverizer”. Today, the Pulverizer is more commonly known as “the extended Euclidean GCD algorithm”, but that’s lame. We’re sticking with “Pulverizer”.

Euclid’s algorithm for finding the GCD of two numbers relies on repeated application of the equation:

\[
\gcd(a, b) = \gcd(b, a \text{ rem } b)
\]

which was proved in lecture (see the notes “Number Theory I”). For example, we can compute the GCD of 259 and 70 as follows:

\[
\begin{align*}
gcd(259, 70) &= gcd(70, 49) & \text{since } 259 \text{ rem } 70 = 49 \\
&= gcd(49, 21) & \text{since } 70 \text{ rem } 49 = 21 \\
&= gcd(21, 7) & \text{since } 49 \text{ rem } 21 = 7 \\
&= gcd(7, 0) & \text{since } 21 \text{ rem } 7 = 0 \\
&= 7.
\end{align*}
\]

The Pulverizer goes through the same steps, but requires some extra bookkeeping along the way: as we compute \( \gcd(a, b) \), we keep track of how to write each of the remainders (49, 21, and 7, in the example) as a linear combination of \( a \) and \( b \) (this is worthwhile, because our objective is to write the last nonzero remainder, which is the GCD, as such a

\footnote{In fact, we proved that among all positive linear combinations of the numbers their GCD is the smallest.}
linear combination). For our example, here is this extra bookkeeping:

\[
\begin{array}{ccc}
\hline
x & y & (x \text{ rem } y) = x - q \cdot y \\
259 & 70 & 49 = 259 - 3 \cdot 70 \\
70 & 49 & 21 = 70 - 1 \cdot 49 \\
& & = 70 - 1 \cdot (259 - 3 \cdot 70) \\
& & = -1 \cdot 259 + 4 \cdot 70 \\
49 & 21 & 7 = 49 - 2 \cdot 21 \\
& & = (259 - 3 \cdot 70) - 2 \cdot (-1 \cdot 259 + 4 \cdot 70) \\
& & = 3 \cdot 259 - 11 \cdot 70 \\
21 & 7 & 0 \\
\hline
\end{array}
\]

We began by initializing two variables, \(x = a\) and \(y = b\). In the first two columns above, we carried out Euclid’s algorithm. At each step, we computed \(x \text{ rem } y\), which can be written in the form \(x - q \cdot y\). (Remember that the Division Algorithm says \(x = q \cdot y + r\), where \(r\) is the remainder. We get \(r = x - q \cdot y\) by rearranging terms.) Then we replaced \(x\) and \(y\) in this equation with equivalent linear combinations of \(a\) and \(b\), which we already had computed. After simplifying, we were left with a linear combination of \(a\) and \(b\) that was equal to the remainder as desired. The final solution is boxed.
2 Problem: The Pulverizer!

There is a pond. Inside the pond there are \( n \) pebbles, arranged in a cycle. A frog is sitting on one of the pebbles. Whenever he jumps, he lands exactly \( k \) pebbles away in the clockwise direction, where \( 0 < k < n \). The frog’s meal, a delicious worm, lies on the pebble right next to his, in the clockwise direction.

(a) Describe a situation where the frog can’t reach the worm.

Solution. If \( k \mid n \) (say \( k = 3 \) and \( n = 6 \)), then no number of jumps will lead the frog to the worm, as the frog will be returning to his original pebble ad infinitum.

(b) In a situation where the frog can actually reach the worm, explain how to use the Pulverizer to find how many jumps the frog will need.

Solution. Suppose the frog can reach the worm. When he actually reaches it, he has jumped a number of times, say \( j \), and he has travelled around the cycle a number of times, call it \( c \). Then, the distance that the frog has covered is both \( j \cdot k \) and \( c \cdot n + 1 \), so that

\[ jk = cn + 1. \]

But this means that 1 can be written as a linear combination of \( n \) and \( k \):

\[ (-c)n + jk = 1. \]

Since 1 is positive, we conclude that it is a positive linear combination of \( n \) and \( k \). And since it is the smallest positive integer, we also conclude that it is the smallest positive linear combination of \( n \) and \( k \). But we have proved in lecture that the smallest positive linear combination of two integers is their GCD. So, the GCD of \( n \) and \( k \) is 1:

\[ \gcd(n, k) = 1 \]

and we can use the Pulverizer to find \(-c\) and \( j\).

(c) Compute the number of jumps if \( n = 50 \) and \( k = 21 \). Anything strange?

Solution. We go through the steps as described in Section 1 (see the table below) to get that \( 1 = 8 \cdot 50 - 19 \cdot 21 \), or \( 1 = -(−8) \cdot 50 + (−19) \cdot 21 \). Hence, \( c = −8 \) and \( j = −19 \), which makes little sense. What does it mean for the frog to make \(-19\) jumps?

The point is that the Pulverizer is guaranteed to give us the integers coefficients of a linear combination that equals the GCD, but it promises nothing about the signs of those coefficients—which, in this case we wanted them to be \(-\) and \(+\). To get coefficients of the desired sign, we have to think more (and much less after the next lecture).

So, we know \( 1 = 8 \cdot 50 - 19 \cdot 21 \). Or, to obtain meaningful signs for the numbers, \( 19 \cdot 21 = 8 \cdot 50 - 1 \). That is, after 19 jumps the frog will have covered 8 full cycles but 1 pebble. So, he will be right next to his original pebble, but in the counter-clockwise direction. Given this, how can he reach the pebble he is after?
Well, if he makes 19 more jumps, he will land 2 pebbles away from his original position in the counter-clockwise direction. Another 19 jumps will lead him 3 pebbles away, and so on. After a total of 49 sets of 19 jumps, he will be 49 pebbles away from its original position in the counter-clockwise direction, which is of course the worm’s pebble. Then, the frog will have made $49 \times 19 = 931$ jumps.

Here is the table produced by the Pulverizer:

<table>
<thead>
<tr>
<th>$x$</th>
<th>$y$</th>
<th>$(x \text{ rem } y) = x - q \cdot y$</th>
</tr>
</thead>
<tbody>
<tr>
<td>50</td>
<td>21</td>
<td>8 = 50 – 2 \cdot 21</td>
</tr>
<tr>
<td>21</td>
<td>8</td>
<td>5 = 21 – 2 \cdot 8</td>
</tr>
<tr>
<td></td>
<td></td>
<td>= 21 – 2 \cdot (50 – 2 \cdot 21)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>= –2 \cdot 50 + 5 \cdot 21</td>
</tr>
<tr>
<td>8</td>
<td>5</td>
<td>3 = 8 – 1 \cdot 5</td>
</tr>
<tr>
<td></td>
<td></td>
<td>= (50 – 2 \cdot 21) – 1 \cdot (–2 \cdot 50 + 5 \cdot 21)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>= 3 \cdot 50 – 7 \cdot 21</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
<td>2 = 5 – 1 \cdot 3</td>
</tr>
<tr>
<td></td>
<td></td>
<td>= (–2 \cdot 50 + 5 \cdot 21) – 1 \cdot (3 \cdot 50 – 7 \cdot 21)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>= –5 \cdot 50 + 12 \cdot 21</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>1 = 3 – 1 \cdot 2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>= (3 \cdot 50 – 7 \cdot 21) – 1 \cdot (–5 \cdot 50 + 12 \cdot 21)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>= 8 \cdot 50 – 19 \cdot 21</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>
3 Problem: The Fibonacci numbers. Again.

Give an inductive proof that the Fibonacci numbers $F_n$ and $F_{n+1}$ are relatively prime for all $n \geq 0$. Recall that the Fibonacci numbers are defined as follows:

\[ F_0 = 0 \quad F_1 = 1 \quad F_n = F_{n-1} + F_{n-2} \quad (\text{for } n \geq 2). \]

**Solution.** We use induction on $n$. Let $P(n)$ be the proposition that $F_n$ and $F_{n+1}$ are relatively prime.

*Base case:* $P(0)$ is true because $F_0 = 0$ and $F_1 = 1$ are relatively prime.

*Inductive step:* We show that, for all $n \geq 0$, $P(n)$ implies $P(n + 1)$. So, fix some $n \geq 0$ and assume that $P(n)$ is true, that is, $F_n$ and $F_{n+1}$ are relatively prime. We will show that $F_{n+1}$ and $F_{n+2}$ are relatively prime as well. We will do this by contradiction.

Suppose $F_{n+1}$ and $F_{n+2}$ are not relatively prime. Then they have a common divisor $d > 1$. But then $d$ also divides the linear combination $F_{n+2} - F_{n+1}$, which actually equals $F_n$. Hence, $d > 1$ divides both $F_n$ and $F_{n+1}$. Which implies $F_n$, $F_{n+1}$ are not relatively prime, a contradiction to the inductive hypothesis.

Therefore, $F_{n+1}$ and $F_{n+2}$ are relatively prime. That is, $P(n + 1)$ is true.

The theorem follows by induction.
4 Problem: The power of 3.

Let $N$ be a number whose decimal expansion consists of $3^n$ identical digits. Show by induction that $3^n | N$. For example:

\[
3^2 \mid \overline{777777777} \quad \text{where } 3^2 = 9 \text{ digits}
\]

Recall that 3 divides a number iff it divides the sum of its digits.

Solution. We proceed by induction on $n$. Let $P(n)$ be the proposition that $3^n | N$, where the decimal expansion of $N$ consists of $3^n$ identical digits.

Base case. $P(0)$ is true because $3^0 = 1$ divides every number.

Inductive step. Now we show that, for all $n \geq 0$, $P(n)$ implies $P(n + 1)$. Fix any $n \geq 0$ and assume $P(n)$ is true. Consider a number whose decimal expansion consists of $3^{n+1}$ copies of the digit $a$:

\[
\underbrace{aaa \ldots aaaa}_{3^{n+1} \text{ digits}} = \underbrace{aaa\ldots aao}_{3^n \text{ digits}} \underbrace{aaa \ldots aoo}_{3^n \text{ digits}} \underbrace{aaa \ldots aoo}_{3^n \text{ digits}}
\]

Now $3^n$ divides the first term by the assumption $P(n)$, and 3 divides the second term since the digits sum to 3. Therefore, the whole expression is divisible by $3^{n+1}$. This proves $P(n + 1)$.

By the principle of induction $P(n)$ is true for all $n \geq 0$.
