

# UMP TESTS & THE KARLIN-RUBIN THEOREM

## Signal Detection in the Presence of Unknowns

In many real world detection problems, the characteristics of the signal and/or noise are not perfectly known:

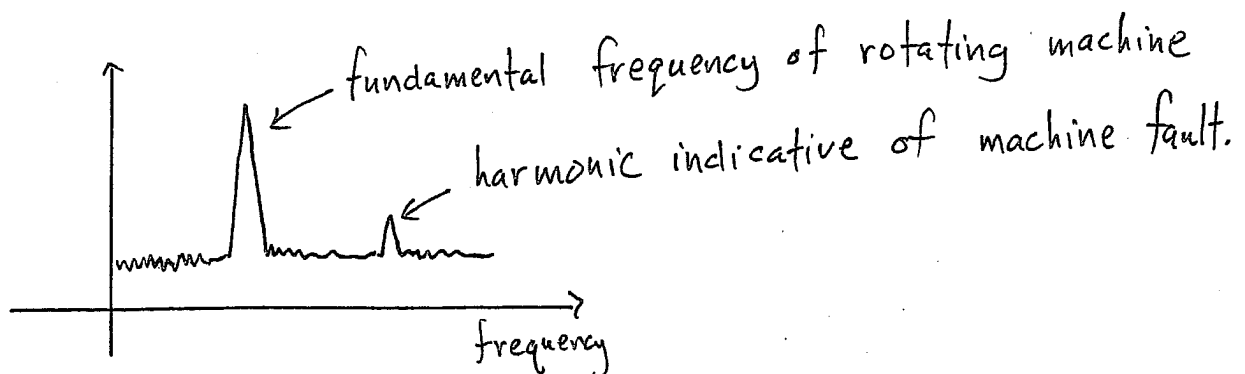

Ex 1 | Unknown signal amplitude

(a) Wireless comm:

received signal attenuated by unknown factor

(b) machine fault detection

strength of harmonic distortion is uncertain

## Ex 2 Unknown location / delay

(a) Radar:

$d = t_1 - t_0$  is unknown

(b) Step-change detection:

$\tau$  unknown

In 2-d, this amounts to edge-detection:  
where do edges occur?

### Ex 3 | Unknown noise power

We may know noise is white, but what is  $\sigma^2$ ?

Heart monitoring:

Goal: detect abnormal heartbeat.

Noise level depends on patient, electrode placement, and ambient noise from environment, all of which may be unknown.

# Modeling Uncertainty

① Parametric uncertainty: unknown parameters in pdf or pmf of observation.

② Nonparametric uncertainty: we don't even know the functional form of the pdf or pmf

Non parametric uncertainty is much more challenging. We will focus on parametric uncertainty in this course.

# Composite Hypothesis Testing

$$H_0: \underline{X} \sim f(\underline{x}; \underline{\theta}_0), \quad \underline{\theta}_0 \in \Theta_0$$

$$H_1: \underline{X} \sim f(\underline{x}; \underline{\theta}_1), \quad \underline{\theta}_1 \in \Theta_1$$

So far, we have only considered simple hypotheses:  $\Theta_0 = \{\theta_0\}$ ,  $\Theta_1 = \{\theta_1\}$ . When

$|\Theta_k| > 1$ ,  $H_k$  is a composite hypothesis.

EX 1 | Unknown mean:

$$H_0: X \sim \mathcal{N}(0, 1)$$

$$H_1: X \sim \mathcal{N}(\mu, 1), \quad \mu > 0$$

$\Rightarrow H_1$  is composite

EX 2 | Unknown noise power

$$H_0: x(n) = s_0(n) + w(n)$$

$$H_1: x(n) = s_1(n) + w(n)$$

$w(n) \stackrel{iid}{\sim} \mathcal{N}(0, \sigma^2)$ ,  $\sigma^2$  unknown  $\Rightarrow H_0, H_1$  composite

Whether we want a Bayes Risk or Neyman-Pearson detector, the optimal decision rule is the LRT:

$$\Lambda(\underline{x}) = \frac{f(\underline{x}; \theta_1)_{H_1}}{f(\underline{x}; \theta_0)_{H_0}} \underset{<}{\overset{\geq}{\gtrless}} \eta$$

In this form, the LRT requires knowledge of the unknown parameter, and hence is not useful.

Sometimes, however, if we write the test in a different form, the dependence on the unknown parameter goes away.

Ex | Signal Detection in AWGN,  $\sigma^2$  unknown:

$$H_0 : \underline{x} = \underline{w}$$

$$w(n) \stackrel{iid}{\sim} \mathcal{N}(0, \sigma^2)$$

$$H_1 : \underline{x} = \underline{s} + \underline{w}$$

$$\sigma^2 \text{ unknown}$$

LRT reduces to

$$\underline{s}^T \underline{x} \underset{H_0}{\overset{H_1}{>}} \sigma^2 \log(\eta) + \frac{\underline{s}^T \underline{s}}{2}$$

If the hypotheses are equally probable a priori, then  $\eta = 1$  and we have

$$\underline{s}^T \underline{x} \underset{H_0}{\overset{H_1}{>}} \frac{\underline{s}^T \underline{s}}{2}$$

independent  
of  $\sigma^2$

For  $M > 2$  hypotheses

$$H_k : \underline{x} = \underline{s}_k + \underline{w}$$

$$\Rightarrow \text{minimize } \frac{1}{\sigma^2} \|\underline{x} - \underline{s}_k\|^2$$

This situation is rare in practice.

A more common occurrence is when the LRT can be reduced to a test statistic that does not depend on the unknown parameter under  $H_0$ . This allows us to set the false alarm rate.

Ex | Unknown signal amplitude

$$H_0 : x(n) = w(n)$$

$$H_1 : x(n) = A s(n) + w(n)$$

$$w(n) \stackrel{i.i.d.}{\sim} \mathcal{N}(0, \sigma^2), \quad \sigma^2 \text{ known, } A \text{ unknown}$$

The LRT reduces to

$$\underbrace{A \underline{s}^T \underline{x}}_{H_0} \underset{H_0}{\stackrel{H_1}{>}} \sigma^2 \log(\eta) + A^2 \frac{\underline{s}^T \underline{s}}{2}$$

↳ test statistic depends on unknown amplitude  $\Rightarrow$  don't know distribution under  $H_0 \Rightarrow$  can't set  $P_F$

What if we know  $A > 0$ ? Then,  
dividing by  $A$ , we have

$$\underline{S}^T \underline{x} \underset{H_0}{\underset{H_1}{>}} \frac{\sigma^2}{A} \log(\eta) + A \frac{\underline{S}^T \underline{S}}{2} \equiv \gamma$$

Under  $H_0$

Ⓐ

$$\underline{S}^T \underline{x} \sim$$

← independent  
of  $A$ !

We can now set the threshold  $\gamma$  to  
achieve a certain  $P_F$ :

$$P_F =$$

$$\implies \gamma =$$

So we can set  $\gamma$  to achieve  $P_F$ . So what?

Is this detector optimal in any sense?

Is  $P_D$  maximized?

Since the LRT is equivalent to

$$\underline{z}^T \underline{x} \underset{H_0}{\overset{H_1}{\gtrless}} \gamma$$

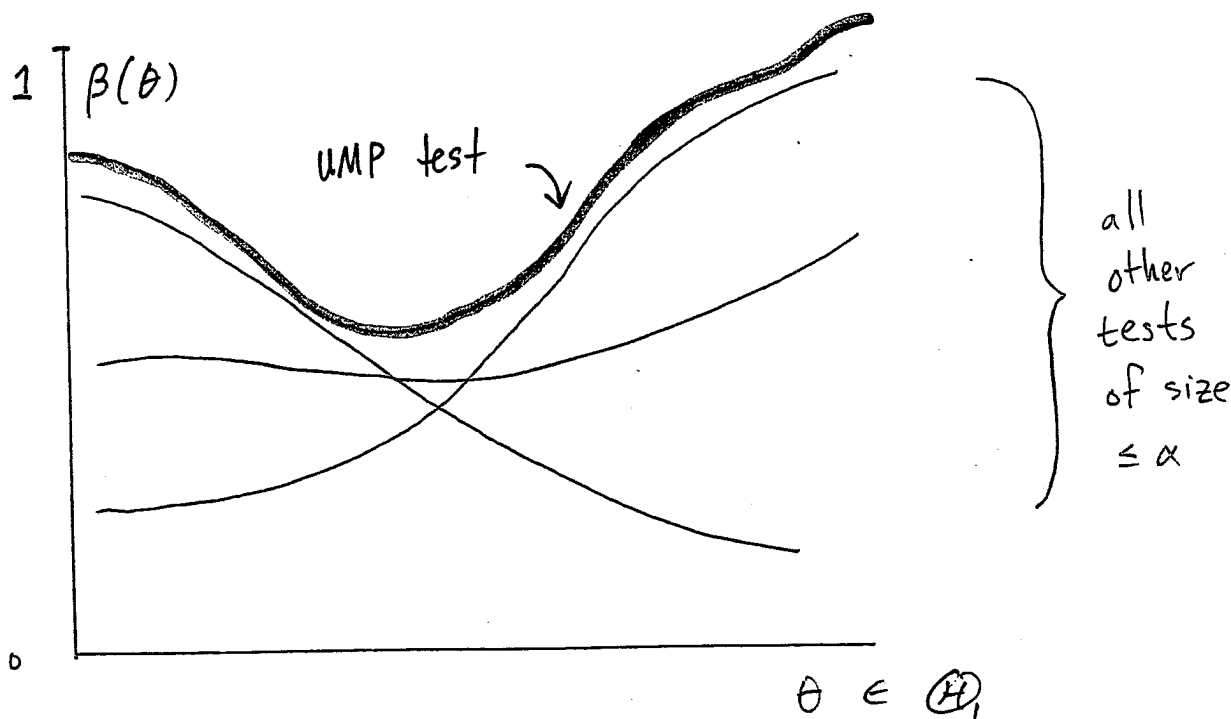

and  $\gamma$  can be selected to ensure  $P_F = \alpha$ , the NP lemma implies that this test is optimal regardless of the value of  $A$ !

### UMP Tests

A test/detector is a uniformly most powerful (UMP) test of size  $\alpha$  if it has the largest power

$$\beta(\theta) := P(\text{declare } H_1; \theta), \quad \theta \in \Theta_1$$

among all tests of size  $\leq \alpha$ ,  $\forall \theta \in \Theta_1$

Unfortunately, UMP tests rarely exist. However, there is a certain class of problems for which they do.

## Monotone Likelihood Ratios

Suppose a measurement  $\underline{x}$  has pdf/pmf determined by a scalar parameter  $\theta$  and let  $\theta_0$  be fixed. Suppose we are interested in the one-sided problem

$$H_0: \theta = \theta_0$$

$$H_1: \theta > \theta_0$$

Further suppose that  $t$  is a scalar sufficient statistic for  $\theta$ .

Observe that for any  $\theta_1 > \theta_0$ , the likelihood ratio is a function of  $t$ :

$$\Lambda(\underline{x}) = \frac{f(\underline{x}; \theta_1)}{f(\underline{x}; \theta_0)} = \frac{a(\underline{x}) b_{\theta_1}(t)}{a(\underline{x}) b_{\theta_0}(t)} = \frac{b_{\theta_1}(t)}{b_{\theta_0}(t)} = \tilde{\Lambda}(t)$$

by the Fisher-Neyman factorization.

Proposition 1 If  $\tilde{\Lambda}(t)$  is monotone increasing for all  $\theta_1 > \theta_0$ , then

$$t \underset{H_0}{\overset{H_1}{\gtrless}} \gamma$$

is UMP of size  $\alpha$ , where  $\alpha$  is determined by

$$P(T > \gamma; \theta = \theta_0) = \alpha.$$

A similar result holds if  $\tilde{\Lambda}(t)$  is monotone decreasing for all  $\theta_1 > \theta_0$ .

Proof Suppose  $\theta = \theta_1 > \theta_0$ . We need to show that

$$P(T > \gamma; \theta = \theta_1)$$

is as large as possible among all tests with size  $\alpha$ . By the NP Lemma, the most powerful test for  $\theta = \theta_1$  vs.  $\theta = \theta_0$  is

$$\tilde{\Lambda}(t) \gtrless \eta$$

where  $\eta$  is such that

$$P(\tilde{\Lambda}(T) > \eta; \theta = \theta_0) = \alpha.$$

Since  $\tilde{\Lambda}(t)$  is monotone increasing, so is its inverse, and the most powerful test simplifies to

$$t \underset{H_0}{\overset{H_1}{\geq}} \tilde{\Lambda}^{-1}(\alpha) \equiv \delta.$$

Since the distribution of  $T; \theta = \theta_0$  is independent of  $\theta_1$ , we can set the value of  $\delta$  without knowledge. In other words, our test has greatest power for all  $\theta_1 > \theta_0$ . □

---

In short, the monotone LR property implies that we can eliminate  $\theta_1$  from the test statistic, and since  $H_0$  is simple, we can set the threshold to ensure the desired size.

Remarks | ① In the case of discrete data, the thresholding test may have the form

$$t \begin{array}{c} H_1 \\ \geq \\ \equiv \\ < \\ H_0 \end{array} \gamma$$

where if  $t = \gamma$  we flip a " $\rho$ -coin" such that

$$P\{T > \gamma; \theta_0\} + \rho P\{T = \gamma; \theta_0\} = \alpha.$$

② If  $\tilde{\lambda}(t)$  is monotone decreasing, then the inequalities in the thresholding test are reversed.

## The Karlin-Rubin Theorem

The preceding result can be generalized to the case where  $\Theta_0$  is also composite.

Now suppose  $\theta_0$  is fixed and consider the one-sided problem

$$H_0: \theta \leq \theta_0$$

$$H_1: \theta > \theta_0$$

To state the general result, we need to generalize our notion of "size."

Let  $\phi(\underline{x}) \in \{0, 1\}$  denote an arbitrary test. We define the size of  $\phi$  by

$$\begin{aligned} \text{size}(\phi) &= \sup_{\theta \in \Theta_0} P\{\phi(\underline{X}) = 1 \mid \theta\} \\ &= \sup_{\theta \in \Theta_0} E_{\theta}\{\phi(\underline{X})\}. \end{aligned}$$

This is essentially the maximum false alarm rate over all possible null hypotheses.

Theorem | Suppose  $t$  is a scalar suff. stat. for  $\theta$  and that

$$\tilde{\Lambda}_{\theta_1, \theta_0}(t) = \frac{b_{\theta_1}(t)}{b_{\theta_0}(t)}$$

is monotone increasing for each  $\theta_1 > \theta_0$ .

Then a UMP test of size  $\alpha$  is given by

$$\phi(t) = \begin{cases} 1 & \text{if } t > \gamma \\ \text{flip a } p\text{-coin} & \text{if } t = \gamma \\ 0 & \text{if } t < \gamma \end{cases}$$

where  $\gamma, p$  are chosen such that

$$P\{T > \gamma \mid \theta = \theta_0\} + pP\{T = \gamma \mid \theta = \theta_0\} = \alpha.$$

Remarks | (1) See Scharf, p 124, for a proof.

(2) Similar result holds if  $\Lambda(t)$  is monotone decreasing.

(3) Similar result applies to the problem

$$H_0 : \theta_{\min} \leq \theta \leq \theta_0$$

$$H_1 : \theta_0 < \theta \leq \theta_{\max}$$

where  $\theta_{\min}, \theta_{\max}$  are fixed and possibly unknown.

When is  $\tilde{\lambda}(t)$  monotone increasing? When the LRT can be reduced to

$$t \underset{H_0}{\overset{H_1}{\geq}} \delta$$

by a series of monotone increasing transformations.

Exercise | Suppose  $X_i \stackrel{iid}{\sim} N(\mu, \sigma^2)$ ,  $i=1, \dots, N$   
and  $\mu$  known, and consider testing

$$H_0: 0 < \sigma^2 \leq \sigma_0^2$$

$$H_1: \sigma^2 \geq \sigma_0^2$$

with  $\sigma_0^2$  fixed, known. Find a UMP test.

Solution | Let  $\sigma_1^2 > \sigma_0^2$ . Then

$$\begin{aligned}\Lambda(\underline{x}) &= \frac{(2\pi\sigma_1^2)^{-\frac{N}{2}} \exp\left\{-\frac{t}{2\sigma_1^2} \sum_{i=1}^N (x_i - \mu)^2\right\}}{(2\pi\sigma_0^2)^{-\frac{N}{2}} \exp\left\{-\frac{1}{2\sigma_0^2} \sum_{i=1}^N (x_i - \mu)^2\right\}} \\ &= \left(\frac{\sigma_0}{\sigma_1}\right)^N \exp\left\{\underbrace{\frac{1}{2}\left(\frac{1}{\sigma_0^2} - \frac{1}{\sigma_1^2}\right) \sum_{i=1}^N (x_i - \mu)^2}_{t}\right\}\end{aligned}$$

Then

$$\Lambda(t) \geq \eta \Leftrightarrow \exp\left\{\frac{1}{2}\left(\frac{1}{\sigma_0^2} - \frac{1}{\sigma_1^2}\right)t\right\} \geq \eta \left(\frac{\sigma_1}{\sigma_0}\right)^N$$

$$\Leftrightarrow \left(\frac{1}{\sigma_0^2} - \frac{1}{\sigma_1^2}\right)t \geq 2 \log\left[\eta \left(\frac{\sigma_1}{\sigma_0}\right)^N\right]$$

$$\Leftrightarrow t \geq \frac{2 \log\left[\eta \left(\frac{\sigma_1}{\sigma_0}\right)^N\right]}{\left(\frac{1}{\sigma_0^2} - \frac{1}{\sigma_1^2}\right)} =: \delta$$

Since  $\sigma_1^2 > \sigma_0^2$ , all steps are monotone

increasing  $\Rightarrow$  UMP test exists.

To set the threshold, recall

$$\frac{T}{\sigma_0^2} = \sum_{i=1}^N \left( \frac{X_i - \mu}{\sigma_0} \right)^2 \sim \chi_N^2 \quad \text{if } \sigma^2 = \sigma_0^2$$

Define

$$Q_{\chi_N^2}(r) := P \{ \chi_N^2 > r \}.$$

Then the size of our test is

$$P \{ T > \gamma ; \sigma^2 = \sigma_0^2 \}$$

$$= P \left\{ \frac{T}{\sigma_0^2} > \frac{\gamma}{\sigma_0^2} ; \sigma^2 = \sigma_0^2 \right\}$$

$$= Q_{\chi_N^2} \left( \frac{\gamma}{\sigma_0^2} \right)$$

$$= \alpha$$

$$\Rightarrow \gamma = \sigma_0^2 Q_{\chi_N^2}^{-1}(\alpha).$$

## Two-Sided Problems

What if we are interested in a slightly different problem?

$$H_0: x(n) = w(n)$$

$$H_1: x(n) = As(n) + w(n), \quad A \neq 0$$

That is

$$H_0: A = 0$$

$$H_1: A \neq 0$$

This is called a two-sided test,  
and UMPs never exist for such tests.  
We must be content with a suboptimal  
detector.

What can we do?

Consider the scalar case:

$$H_0: X \sim \mathcal{N}(0, \sigma^2)$$

$\sigma^2$  known

$$H_1: X \sim \mathcal{N}(A, \sigma^2)$$

$A \neq 0$ , unknown

Intuitively, the decision rule

$$|x| \underset{H_0}{\overset{H_1}{\gtrless}} \gamma$$

comes to mind.

Large excursions of the observation  $x$  from 0 may indicate the signal is present.

$H_0$  does not depend on  $A$ , so we may set the threshold  $\gamma$  by constraining  $P_F$ :

$$P_F = 2 \int_{\gamma}^{\infty} \frac{1}{\sqrt{2\pi\sigma^2}} e^{-x^2/2\sigma^2} dx = 2Q\left(\frac{\gamma}{\sigma}\right)$$

$$\Rightarrow \gamma = \sigma Q^{-1}\left(\frac{P_F}{2}\right)$$

In terms of  $A$ , the detection probability is

⑥  $P_D =$

To evaluate our suboptimal detector, we can compare it to the clairvoyant detector, which assumes full knowledge of unknowns.

What is the clairvoyant detector for this problem (unknown amplitude)?

If  $A > 0$ ,

$$x \underset{H_0}{\overset{H_1}{>}} \gamma \equiv \frac{\sigma^2}{A} \log(\eta) + \frac{A}{2}$$

©  $\Rightarrow P_F =$

$\gamma =$

$P_D =$

If  $A < 0$

$$X \begin{cases} > \\ < \end{cases} \begin{matrix} H_0 \\ H_1 \end{matrix} \frac{\sigma^2}{A} \log(\eta) + \frac{A}{2} \equiv \gamma$$

inequalities reversed

$$\Rightarrow P_F = 1 - Q\left(\frac{\gamma}{\sigma}\right) = Q\left(\frac{-\gamma}{\sigma}\right)$$

$$\gamma = -\sigma Q^{-1}(P_F)$$

$$P_D = 1 - Q\left(\frac{\gamma - A}{\sigma}\right) = Q\left(\frac{A - \gamma}{\sigma}\right) \\ = Q\left(Q^{-1}(P_F) + \frac{A}{\sigma}\right)$$

Summary

$$A > 0: P_D = Q\left(Q^{-1}(P_F) - \frac{A}{\sigma}\right)$$

$$A < 0: P_D = Q\left(Q^{-1}(P_F) + \frac{A}{\sigma}\right)$$

We can combine these to obtain

$$P_D = Q\left(Q^{-1}(P_F) - \sqrt{\frac{A^2}{\sigma^2}}\right)$$

for all  $A \neq 0$ .

$$P_F = 0.5, \quad \sigma^2 = 0.5$$

Clairvoyant:  $P_D = Q(Q^{-1}(P_F) - \sqrt{\frac{A^2}{\sigma^2}})$

Suboptimal:  $P_D = Q(Q^{-1}(\frac{P_F}{2}) - \sqrt{\frac{A^2}{\sigma^2}})$

$$+ Q(Q^{-1}(\frac{P_F}{2}) + \sqrt{\frac{A^2}{\sigma^2}})$$

Let's return to the vector case:

$$H_0: \underline{x} = \underline{w}$$

$$H_1: \underline{x} = A\underline{s} + \underline{w}, \quad A \neq 0$$

How might we generalize our previous detector?

Recall the LRT reduces to

$$A\underline{s}^T \underline{x} \underset{H_0}{\overset{H_1}{\gtrless}} \sigma^2 \log(\eta) + A^2 \frac{\underline{s}^T \underline{s}}{2}$$

For a suboptimal detector we could take

$$|\underline{s}^T \underline{x}| \underset{H_0}{\overset{H_1}{\gtrless}} \gamma$$

Exercise Derive  $P_D$  as a function of  $A$ ,  $P_F$ ,  $\underline{s}$ , and  $\sigma^2$ , and compare to clairvoyant detector.

## Summary

- Most real-world detection problems involve un
- In very special cases: LRT<sup>s</sup> independent of unk
- One-sided problems: If LR is monotone, UA test exists.
- Two-sided problems: UMP tests never exist, but reasonable suboptimal detectors do.
- Next lecture: General strategies for devising suboptimal detectors when no UMP test exists.

Key

a.  $\underline{\Sigma}^T \underline{x} \sim N(0, \sigma^2 \underline{\Sigma}^T \underline{\Sigma})$  under  $H_0$

$$P_F = P(\underline{\Sigma}^T \underline{x} > \gamma \mid H_0) = Q\left(\frac{\gamma}{\sigma \sqrt{\underline{\Sigma}^T \underline{\Sigma}}}\right) = \alpha$$

$$\Rightarrow \gamma = \sigma \sqrt{\underline{\Sigma}^T \underline{\Sigma}} Q^{-1}(\alpha)$$

b.  $P_D = P(|X| > \gamma \mid H_1) = P(X > \gamma \mid H_1) + P(X < -\gamma \mid H_1)$   
 $= Q\left(\frac{\gamma - A}{\sigma}\right) + Q\left(\frac{\gamma + A}{\sigma}\right)$

c.  $P_F = Q\left(\frac{\gamma}{\sigma}\right)$ ,  $\gamma = \sigma Q^{-1}(P_F)$ ,

$$P_D = Q\left(\frac{\gamma - A}{\sigma}\right) = Q\left(Q^{-1}(P_F) - \frac{A}{\sigma}\right)$$
