Image Reconstruction

object $f$ → System → $\oplus$ → measured data $y$ → Reconstruction → $\hat{f}$

noise

Formulations

- Static $f(\vec{r})$
- Dynamic $f(\vec{r}, t)$
  - contrast changes
  - object motion

(synergy with image registration)
Part 1
Image registration
ensuring local invertibility
Image Registration

Many applications, e.g., forensics, remote sensing, medicine ...
- rigid transformations
- nonrigid transformations (warps)

Example: Respiratory motion
Image registration: Overview

Given two images (or image volumes): \( f(\vec{r}) \) and \( g(\vec{r}) \), \( \vec{r} = (x, y, z) \), find a spatial transformation \( \vec{T}(\vec{r}) \), where \( \vec{T} : \mathbb{R}^3 \rightarrow \mathbb{R}^3 \), such that \( f(\vec{r}) \) "is similar to" the warped image \( g(\vec{T}(\vec{r})) \)

Usual steps:

- parameterize by \( \alpha \) the spatial transformation: \( \vec{T}(\vec{r}; \alpha) \)
- choose a similarity measure \( \Psi(f(\cdot), g(\vec{T}(\cdot))) \)
- find optimal deformation parameters \( \alpha \) numerically:
  \[
  \hat{\alpha} = \arg \max_{\alpha} \Psi(f(\cdot), g(\vec{T}(\cdot; \alpha)))
  \]

Challenge: want estimated transformation \( \vec{T}(\vec{r}; \hat{\alpha}) \) to be plausible. Typically we want it to be diffeomorphic, or topology preserving, or invertible, or at least locally invertible.
Image registration: Similarity measures

sum of squared differences

correlation

mutual information

...
Image registration: B-spline deformations

Nonrigid spatial transformation:

\[ \tilde{T}(\vec{r}; \alpha) = \vec{r} + \left( d^x(\vec{r}; \alpha^x), d^y(\vec{r}; \alpha^y), d^z(\vec{r}; \alpha^z) \right), \]

deformation

where \( \alpha = (\alpha^x, \alpha^y, \alpha^z) \) denotes unknown deformation coefficients.

Tensor-product B-spline deformation model:

\[ d^x(\vec{r}; \alpha^x) = \sum_{i,j,k} \alpha_{ijk}^x \beta(x/m_x - i) \beta(y/m_y - j) \beta(z/m_z - k) \]

\[ d^y(\vec{r}; \alpha^y) = \sum_{i,j,k} \alpha_{ijk}^y \beta(x/m_x - i) \beta(y/m_y - j) \beta(z/m_z - k) \]

\[ d^z(\vec{r}; \alpha^z) = \sum_{i,j,k} \alpha_{ijk}^z \beta(x/m_x - i) \beta(y/m_y - j) \beta(z/m_z - k) \]

\( m_x, m_y, m_z \) denote the knot spacing in each dimension. These spacings determine the spatial scale of the deformation.
B-spline deformations: Benefits

- differentiable (smooth)
- local support
- recursive filters for computations
- piecewise polynomial
- hierarchical

Nonrigid image registration similarity measures usually have many local maximizers. To help find a “good” local maximum, one usually uses coarse-to-fine search. This is easy with B-spline deformations.

(Thevenaz & Unser, IEEE T-IP, 2000)

Invertible

Not invertible
Invertibility

When is \( \vec{r} \mapsto \vec{T}(\vec{r}) = \vec{r} + \vec{d}(\vec{r}) \) a locally invertible transformation?

By the inverse function theorem, it suffices for \( \vec{T} \) to
- be continuously differentiable, and
- have positive Jacobian determinant: \( \det \left\{ \nabla \vec{T}(\vec{r}) \right\} > 0 \) for all \( \vec{r} \).

Jacobian of transformation/deformation

\[
\nabla \vec{T}(\vec{r}) = \nabla \left( \vec{r} + \vec{d}(\vec{r}) \right) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} + \begin{bmatrix} \frac{\partial}{\partial x} d^x & \frac{\partial}{\partial y} d^x & \frac{\partial}{\partial z} d^x \\ \frac{\partial}{\partial x} d^y & \frac{\partial}{\partial y} d^y & \frac{\partial}{\partial z} d^y \\ \frac{\partial}{\partial x} d^z & \frac{\partial}{\partial y} d^z & \frac{\partial}{\partial z} d^z \end{bmatrix}
\]

(mathematical theory vs practice)
Ensuring local invertibility

We need to estimate B-spline deformation coefficients $\alpha$ subject to some local invertiblity constraint $\alpha \in C$:

$$\hat{\alpha} = \arg \max_{\alpha \in C} \Psi(\alpha).$$

- Ideal local invertibility condition for parametric deformation model:

  $$\alpha \in C_0 = \left\{ \alpha : \det \left\{ \nabla \vec{T}(\vec{r}; \alpha) \right\} > 0, \forall \vec{r} \in \mathbb{R}^3 \right\}.$$  

  This condition is very difficult to implement.

- Conventional relaxed local invertibility condition: $C_0 \subset C_1$

  $$\alpha \in C_1 = \left\{ \alpha : \det \left\{ \nabla \vec{T}(\vec{r}; \alpha) \right\} > 0, \vec{r} \in \text{grid points} \right\}.$$  

  This condition does not ensure local invertibility everywhere. It is also computationally demanding.

We seek simpler sufficient conditions for local invertibility: $C \subset C_0$. 
Unconstrained vs “constrained” optimization

Image registration is an ill-posed problem. Jacobian constraint on grid required $> 3 \times$ computation as unconstrained case. Nevertheless, some negative Jacobians remain (between grid points) because $C_0 \subset C_1$. We need a simpler constraint that ensures positive Jacobian determinants everywhere.
A sufficient condition: Box constraints

Simple lower/upper bounds on B-spline coefficients:

$$\alpha \in C_3 = \left\{ \alpha : \left| \alpha_{ij}^x \right| \leq \frac{m_x}{K}, \left| \alpha_{ij}^y \right| \leq \frac{m_y}{K}, \left| \alpha_{ij}^z \right| \leq \frac{m_z}{K}, \forall i, j, k \right\},$$

where $K \approx 2.05$ in 2D and $K \approx 2.48$ in 3D.
Choi et al., 2000; Rueckert et al., MICCAI 2006

Fact: $C_3 \subset C_0$.
So constraining $\alpha \in C_3$ ensures local invertibility everywhere.

Box constraints are particularly simple for optimization.

However, $C_3$ is a very restrictive set of deformations.
  * Maximum displacement is only about half the knot spacing.
  * Precludes even simple (large) global translations.
Proposed sufficient condition for invertibility

Theorem:
Suppose \(0 \leq k_q < \frac{1}{2}\) for \(q \in \{x, y, z\}\). Define the set:

\[
C_4 = \{ \alpha : -m_x k_x \leq \alpha_{i+1,j,k}^x - \alpha_{i,j,k}^x \leq m_x K_x, \\
- m_y k_y \leq \alpha_{i,j+1,k}^y - \alpha_{i,j,k}^y \leq m_y K_y, \\
- m_z k_z \leq \alpha_{i,j,k+1}^z - \alpha_{i,j,k}^z \leq m_z K_z, \\
|\alpha_{i+1,j,k}^q - \alpha_{i,j,k}^q| \leq m_q k_q \text{ for } q = y, z, \\
|\alpha_{i,j+1,k}^q - \alpha_{i,j,k}^q| \leq m_q k_q \text{ for } q = x, z, \\
|\alpha_{i,j,k+1}^q - \alpha_{i,j,k}^q| \leq m_q k_q \text{ for } q = x, y, \forall i, j, k \}.
\]

If \(\alpha \in C_4\), then \(\forall \vec{r} \in \mathbb{R}^3\):

\[
1 - (k_x + k_y + k_z) \leq \det \left\{ \nabla \vec{T}(\vec{r}; \alpha) \right\} \\
\leq (1 + K_x)(1 + K_y)(1 + K_z) + (1 + K_x)k_y k_z + k_x (1 + K_y) k_z + k_x k_y (1 + K_z).
\]

Corollary:
Choosing \(k_x = k_y = k_z = 1/3 - \varepsilon\) ensures that \(0 < \det \left\{ \nabla \vec{T}(\vec{r}; \alpha) \right\}, \forall \vec{r}\).
Comparing sufficient conditions

1D example with two coefficients: $\alpha_1$, $\alpha_2$, for $n = 2$ (quadratic B-splines)
Limitations of sufficient conditions

2D simulations using augmented Lagrange multiplier approach to enforce the constraint \( \alpha \in C_3 \) or \( \alpha \in C_4 \).

Clearly \( C_3 \subset C_0 \) and \( C_4 \subset C_0 \).
Solution: composition of transformations

Composing multiple transformations can overcome the limitations of sufficient conditions, e.g., \( \overrightarrow{T} \triangleq \overrightarrow{T_{\alpha_3}} \circ \overrightarrow{T_{\alpha_2}} \circ \overrightarrow{T_{\alpha_1}} \) where \( \alpha_1, \alpha_2, \alpha_3 \in C_4 \).
Composition for box constraints

Requires many more compositions:

Rueckert et al., MICCAI 2006

Each of the 30 warps used many augmented Lagrangian iterations. Tradeoff: simplicity of constraint and its flexibility.
Simplyfing further via regularization

Idea: replace constrained optimization

\[ \hat{\alpha} = \arg \max_{\alpha \in C_4} \Psi(\alpha) \]

with simpler unconstrained, but regularized, optimization:

\[ \hat{\alpha} = \arg \max_{\alpha} \Psi(\alpha) - \gamma R(\alpha) \]

where \( R(\alpha) \) is zero if \( \alpha \in C_4 \) but is “large” otherwise. This *encourages* local invertibility, but does not enforce it strictly.

The regularization parameter \( \gamma \) controls the tradeoff between

- image similarity
- regularity of the deformation (local invertibility).
Proposed regularizer

Interval constraints in $C_4$ replaced by piecewise quadratic penalty function of differences of neighboring B-spline coefficients. *cf.* conventional quadratic roughness regularization

$$m_x = m_y = m_z = 1, k_x = k_y = k_z = 1/3, \text{ and } K_x = K_y = K_z = 4/3.$$
Regularization tradeoffs

As regularization parameter $\gamma \uparrow$
- # of negative Jacobian determinants $\downarrow$ so
- RMS difference between images $\uparrow$

Proposed regularizer: good image similarity, few negative Jacobian determinants.
3D registration of CT inhale/exhale scans

Computation time per iteration (in seconds) at the finest level

Regularization parameter adjusted empirically in both penalized cases to be the smallest value that yields no negative Jacobian determinants on the voxel grid.

3 multiresolution levels: knot spacings 8 pixels with downsampled images, 8 pixels with original images, 4 pixels with original images. 120 iterations of CG at each level.

Work in progress to compose a couple coarse-scale deformations before refining to fine scale to reduce RMS differences.

Code on web site: http://www.eecs.umich.edu/~fessler
Diffeomorphisms: To be or not to be...

Sliding at diaphragm / rib cage interface. Enforcing smoothness leads to bone warping.
Requiring the warp to be smooth everywhere seems suboptimal. One possible solution submitted to SPIE 2009. Stay tuned...
Summary

- Simple condition for ensuring local invertibility everywhere
- Admits more deformations than conventional box constraints
- Simple regularizer requires comparable computation as unregularized image registration and much less computation than Jacobian determinant constraints / penalties

Open problems

- Rigid structures (bones)
- Sliding tissue interfaces
- Parameter selection
- Computation (GPUs?)
- Performance characterization
Part 2
Model-based image reconstruction with motion compensation
Motion in image reconstruction

Object being scanned: \( f(\vec{r}, t) \)
Measured data vector: \( y = (y_1, \ldots, y_M) \)

Static image reconstruction:
- Assume \( f(\vec{r}, t) = f(\vec{r}, t_0) = f(\vec{r}) \) during scan.
- Estimate \( f(\vec{r}) \) from measurements \( y \). (Ill posed.)

Dynamic image reconstruction ("List-mode" data model)
- Assume each data point \( y_i \) is acquired instantaneously at a corresponding time instant \( t_i \)
- Relate \( y_i \) to object at time \( t_i \), e.g.,

\[
y_i = \int a_i(\vec{r}) \ f(\vec{r}, t_i) \, d\vec{r} + \varepsilon_i.
\]

More generally: \( p(y_i | f(\cdot, t_i)) \).
- Estimate \( f(\vec{r}, t) \) from measurements \( y \). (Even "more" ill posed!)
Gated data model

- Group data into $K$ vectors, e.g., $K$ respiratory phases: $y_1, \ldots, y_K$
- Assume $f(\vec{r}, t)$ is stationary during $k$th phase of data acquisition
- Relate $y_k$ to $f_k(\vec{r}) \triangleq f(\vec{r}, t_k)$ using physics and statistics
- From $K$ data vectors $y_1, \ldots, y_K$, reconstruct object: ?

\[\hat{f}\]
Gated data: Image reconstruction options

- Pool all data and ignore motion
  - fast
  - low noise variance
  - motion induced blur

- Frame-wise: reconstruct each gate/frame separately: \( y_k \mapsto \hat{f}_k \)
  - simple
  - high noise variance
  - no motion blur (except within-gate motion)

- Frame-wise with post-reconstruction averaging (FW-PRA)
  - map each reconstructed frame onto 1st frame, then average
  - averaging should reduce noise
  - should avoid motion blur if registration is accurate
  - registration accuracy limited by noise in the individual gates

- FW-PRA with motion estimates from a separate modality
  - use another modality (e.g., PET-CT) to estimate motion
  - performance depends on consistency of motion between modalities
  - Thorndyke et al., Med Phys, 2006

...
Frame-wise with post-reconstruction averaging

\[ \hat{f} = \frac{1}{K} \sum_{k=1}^{K} \hat{\alpha}_k \]

\[ \hat{\alpha}_k \]

Common target image

SSD registration

Image Reconstruction

Post-Registration

Consolidation
Forward model with motion

Post-reconstruction averaging assumes an implicit model that relates the frames $f_2, \ldots, f_K$ to the first frame $f_1$.

We now make the (motion) model explicit:

$$f_k = \mathbf{W}(\alpha_k) f_1, \quad k = 2, \ldots, K.$$ 

$\mathbf{W}(\alpha_k)$ is the linear (!) transformation of the image values corresponding to motion $\alpha_k$.

This model suggests additional image reconstruction approaches.
Linear interpolation and Nonrigid deformations

B-spline interpolation model for continuous-space image:

\[ f(\vec{r}) = f(x, y, z) = \sum_{n,m,l} c_{nml} \beta(x-n) \beta(y-m) \beta(z-l) \]

Find coefficients \( c = \{c_{nml}\} \) by prefiltering digital image \( f[n, m, l] \).

Nonrigid deformation of \( f \):

\[ g(\vec{r}) = f(\vec{T}(\vec{r}; \alpha)) = \sum_{n,m,l} c_{nml} \beta(T^x(\vec{r}; \alpha) - n) \beta(T^y(\vec{r}; \alpha) - m) \beta(T^z(\vec{r}; \alpha) - l). \]

Resample warped image on grid (of target image):

\[ g(\vec{r}_j) = \sum_{n,m,l} c_{nml} W_{\vec{r}_j; n,m,l}(\alpha), \quad j = 1, \ldots, N \]

\[ W_{\vec{r}; n,m,l}(\alpha) \triangleq \beta(T^x(\vec{r}; \alpha) - n) \beta(T^y(\vec{r}; \alpha) - m) \beta(T^z(\vec{r}; \alpha) - l) \]

In matrix-vector form, where \( g = \{g(\vec{r}_j)\} \) and \( f = \{f[n, m, l]\} \):

\[ g = W(\alpha)c, \quad c = W^{-1}(0)f \implies g = W(\alpha)W^{-1}(0)f. \]
Forward model with motion

Motion Model

\[ f_1 \]

\[ W(\alpha_2) f_1 \]

\[ \vdots \]

\[ W(\alpha_K) f_1 \]

Acquisition Process

\[ A \]

\[ \epsilon_1 \]

\[ \epsilon_2 \]

\[ \epsilon_K \]

Measured Data

\[ y_1 \]

\[ y_2 \]

\[ \vdots \]

\[ y_K \]
Gated data: More image reconstruction options

- Model-based image reconstruction with motion compensation
  - given motion estimates, from FW-PRA or from separate modality,
  - compensate for motion in reconstruction process.
  - Qiao et al., PMB 2006; Taguchi et al., SPIE 2007.

- Model-based image reconstruction jointly with registration
  - Odille et al., MRM 2008
  - estimate jointly the first frame and the motion from all data

- Model-based image reconstruction with temporal regularization
  - Mair et al., IEEE T-MI, 2006
  - estimate all frames and the motion between frames from all data
Model-based image reconstruction with motion compensation

- Given: motion estimates \( \hat{\alpha}_k \) for \( k = 2, \ldots, K \), from FW approach or from a separate modality,
- model for system physics / statistics: \( p(y_k | f_k) = p(y_k | W(\hat{\alpha}_k) f_1) \).

Perform penalized-likelihood (aka MAP) estimation of one image:
\[
\hat{f}_1 = \arg \max_{f_1} \Psi(f_1; \hat{\alpha}_2, \ldots, \hat{\alpha}_K; y_1, \ldots, y_K)
\]
\[
\Psi(f_1; \hat{\alpha}_2, \ldots, \hat{\alpha}_K; y_1, \ldots, y_K) \triangleq \sum_{k=1}^{K} \log p(y_k | W(\hat{\alpha}_k) f_1) - \beta R(f_1).
\]

\( R(f) \) is optional regularization to control noise in ill-posed image reconstruction problems.

For linear model with additive gaussian noise \( y_k = A_k f_k + \epsilon_k \):
\[
\hat{f}_1 = \arg \min_{f_1} \sum_{k=1}^{K} \| y_k - A_k W(\hat{\alpha}_k) f_1 \|^2 + \beta R(f_1).
\]
Motion compensated image reconstruction

\[
\arg\max_{f_1} \Psi(f_1; \hat{\alpha}_2, \ldots, \hat{\alpha}_K; y_1, \ldots, y)\]

\[
y_1 \rightarrow \text{common source image}
\]

\[
y_2 \rightarrow \hat{\alpha}_2
\]

\[
\cdots
\]

\[
y_K \rightarrow \hat{\alpha}_K
\]

\[
\text{Image Reconstruction} \quad \text{Post-Registration} \quad \text{Consolidation}
\]

SSD registration
Joint image reconstruction / registration

Previous approach used possibly suboptimal motion estimates:

$$\hat{f}_1 = \arg \max_{f_1} \Psi(f_1; \hat{\alpha}_2, \ldots, \hat{\alpha}_K; y_1, \ldots, y_K)$$

Alternative: jointly estimate one image and $K-1$ deformation parameters:

$$(\hat{f}_1, \hat{\alpha}_2, \ldots, \hat{\alpha}_K) = \arg \max_{f_1, \alpha_2, \ldots, \alpha_K} \Psi(f_1; \alpha_2, \ldots, \alpha_K; y_1, \ldots, y_K)$$

$$\Psi(f_1; \alpha_2, \ldots, \alpha_K; y_1, \ldots, y_K) = \sum_{k=1}^{K} \log p(y_k | W(\alpha_k) f_1) - \beta R(f_1)$$

Natural optimization strategy is to alternate between:
- updating image estimate $\hat{f}_1$ using current motion parameters,
- updating motion estimates $\{\hat{\alpha}_k\}$ using current image estimate.

Can initialize motion parameters using frame-wise method.
Joint estimation illustrated

Goal: find image estimate and motion parameters that best fit all measured data.
Motion-compensated temporal regularization

Previous joint estimation approach:

\[
(\hat{f}_1, \hat{\alpha}_2, \ldots, \hat{\alpha}_K) = \arg \max_{f_1, \alpha_2, \ldots, \alpha_K} \Psi(f_1; \alpha_2, \ldots, \alpha_K; y_1, \ldots, y_K)
\]

Alternative approach based on temporal regularization:

\[
(\hat{f}_1, \ldots, \hat{f}_K; \hat{\alpha}_2, \ldots, \hat{\alpha}_K) = \arg \max_{f_1, \ldots, f_K; \alpha_2, \ldots, \alpha_K} \Psi(f_1, \ldots, f_K; \alpha_2, \ldots, \alpha_K; y_1, \ldots, y_K)
\]

\[
\Psi(f_1, \ldots, f_K; \alpha_2, \ldots, \alpha_K; y_1, \ldots, y_K) = \sum_{k=1}^{K} \log p(y_k | f_k) - \beta R(f_k)
\]

\[- \gamma \sum_{k=2}^{K} \| f_{k+1} - \mathbf{W}(\alpha_k) f_k \|^2 \]

Pro: no warp in log-likelihood. Con: more unknowns; \( \gamma \) choice?
