EECS 482
Introduction to Operating Systems

Winter 2019

Manos Kapritsos

Thanks to Harsha Madhyastha and Peter Chen for the slides and notes
CPU scheduling

- If >1 thread/process is ready, which to run?
  - Example, FIFO scheduling in project 2

- Many possible scheduling policies
  - Goal today is to explore fundamental ones
  - Real schedulers often a complex mix of policies
Scheduling: Goals

- What are good goals for a CPU scheduler?
Maximize Performance

- Minimize average response time
  - Elapsed time to do each job
- Maximize throughput of entire system
  - Rate at which jobs complete in the system
Latency-throughput curves

- Collected from Facebook production service [Chow ‘16]
  - Each colored line: throughput vs. response at different quality
  - Left of graph – adding load has little effect on response time
  - Right of graph – adding load causes exponential increase in latency
Fairness

- Share CPU among threads in equitable manner

- How to share between 1 big and 1 small job?
  - Response time proportional to job size?
  - Or equal time for each job?

- Fairness often conflicts with response time
Starvation = extremely unfair

- Starvation can be outcome of synchronization
  - Example: Readers can starve writers

- Starvation can also be outcome of scheduling
  - Example: always run highest-priority thread
  - If many high priority threads, low priority starves
First-come, first-served (FCFS)

- FIFO ordering among jobs
- No preemption (no timer interrupts)
  - Thread runs until it calls yield() or blocks
FCFS Example

- Job A: Arrives at t=0, takes 100 seconds
- Job B: Arrives at t=0+, takes 1 second

\[ \text{A's response time} = 100 \]
\[ \text{B's response time} = 101 \]
\[ \text{Average response time} = 100.5 \]
FCFS Summary

- **Pros:**
  - Simple to implement

- **Cons:**
  - Short jobs can be stuck behind long ones
  - Bad for interactive workloads
Round Robin

- Improve average response time for short jobs
- Still FIFO ordering
- Add preemptions (via timer interrupts)
  - Fixed time slice (time quantum)
  - Preempt if still running when time slice is over
Round Robin Example

- Job A: Arrives at $t=0$, takes 100 seconds
- Job B: Arrives at $t=0+$, takes 1 second

- A’s response time = 101
- B’s response time = 2
- Average response time = 51.5
Choosing a time slice

- What’s the problem with a big time slice?

- What’s the problem with a small time slice?

- OS typically compromises: e.g., 1ms or 10ms
Round Robin Summary

● Pros:
  • Still pretty simple
  • Good for interactive computing

● Cons
  • More context-switching overhead

● Comparison: Does RR always reduce response time vs. FCFS?
STCF

- Shortest time to completion first

- Run job with least work to do
  - Preempt current job if shorter job arrives
  - “work to do” is the time to next blocking operation

- Finish short jobs first
  - Improves response time of short jobs (by a lot)
  - Hurts response time of long jobs (by a little)

- STCF gives optimal average response time
Consider 2 jobs: A longer than B

Average response time \((2A+B)/2\) vs. \((A+2B)/2\)

\(B < A\), so 2\(^{nd}\) has smaller avg. response time

Apply iteratively (e.g., bubble sort) to minimize
STCF Example

- Job A: Arrives at \( t=0 \), takes 100 seconds
- Job B: Arrives at \( t=0^+ \), takes 1 second

- A’s response time = 101
- B’s response time = 1
- Average response time = 51
STCF

- Pro:
  - Optimal average response time

- Cons?
Predicting job run times

- Ask the job or the user?

- Use past to predict future
  - If already run for \( n \) seconds, likely to run for \( n \) more

- OS schedulers often identify interactive apps and boost their priority.
Priority

- Priority
  - Assign external priority to each job
  - Run high-priority jobs before low-priority ones
  - Use, e.g., round-robin for jobs of equal priority
  - Prone to starvation

- Methods for preventing starvation?
  - If job has not run for time t, boost priority
  - Handle priority inversion (lock held by low-priority)
Multimedia: Soft real-time

- Often requires fixed amount of CPU
  - Audio should not skip when compiling projects
  - Predictable: video player plays n frames per second

- Can reserve a share of the CPU
  - X% of the CPU over some time interval
  - Unused CPU split among remaining jobs
Hard real-time scheduling

- Jobs have to complete before deadline
  - Demand / deadline known in advance
  - Example: vehicle control, aviation, etc.

- Earliest-deadline first (EDF)
  - Always run jobs whose deadline is soonest
  - Preempt if newly arriving job has earlier deadline
  - Always succeeds if schedule is feasible
  - But, may be very poor if schedule is infeasible
Scheduling: Summary

- Many different policies
  - FCFS
  - Round robin
  - STCF
  - Priority
  - Proportional share
  - EDF

- OS schedulers mix all of these
  - Many heuristics and complex tuning
  - No perfect solution
