ALPHA VERSION OF TEXT

April 13, 2008

Dedicated to TBD.

Contents

List of Program Examples

List of Figures

Preface

The focus in this book is on teaching data structures as a way to solve problems in modeling the world and executing (simulating) the resultant model. We cover the standard data structures topics (e.g., arrays, linked lists, trees, graphs, stacks, and queues) but in the context of modeling situations then creating simulations (often generating animations).

The presumption is that the reader has had *some* previous programming experience. We expect that the reader can build programs that use iteration via **while** and **for**, and that the reader can assemble that program using functions that pass input via arguments. The reader should know what an array and matrix are. But we don't care what language that previous experience is in.

We use DrJava in examples in this text. *It is not necessary to use DrJava to use this book!* The advantage of DrJava is a simple interface and a powerful interactions pane, which allows us to manipulate objects without writing new methods or classes for each exploration. Rapid iteration allows students to explore and learn a wide space more quickly than they might if each exploration required a new Java file or method.

Typographical notations

Examples of Java code look like this: `x = x + 1`. Longer examples look look like this:

```
public static void main(String[] args){
    System.out.println("Hello, World!");
    }
```

When showing something that the user types in with DrJava's response, it will have a similar font and style, but the user's typing will appear after a prompt (>):

```
> int a = 5;
> a + 7
12
```

User interface components of DrJava will be specified using a smallcaps font, like SAVE menu item and the LOAD button.

There are several special kinds of sidebars that you'll find in the book.

Utility Program

Utility #1: An Example Utility

Utility programs are new pieces with which we will construct our models–not necessarily to be studied for themselves, but offered as something interesting to study and expand upon. They appear like this:

```
public class Greeter
{
  public static void main(String[] argv)
  {
    // show the string "Hello World" on the console
    System.out.println("Hello World");
  }
}
```

Program Example #0

Example Java Code: **An Example Program**

A program creates a model of interest to us.

```
import jm.music.data.*;
import jm.JMC;
import jm.util.*;
import jm.music.tools.*;

public class Dot03  {
    public static void main(String[] args) {
        Note n = new Note(JMC.C4, JMC.QUARTER_NOTE);
        Phrase phr = new Phrase(0.0);
        phr.addNote(n);
        Mod.repeat(phr, 15);

        Phrase phr2 = new Phrase(0.0);
        Note r = new Note(JMC.REST, JMC.EIGHTH_NOTE);
        phr2.addNote(r);
        Note n2 = new Note(JMC.E4, JMC.EIGHTH_NOTE);
        phr2.addNote(n2);
        Note r2 = new Note(JMC.REST, JMC.QUARTER_NOTE);
        phr2.addNote(r2);
        Mod.repeat(phr2, 7);

        Part p = new Part();
        p.addPhrase(phr);
        p.addPhrase(phr2);

        View.show(p);
    }
```

```
28 }
```

Computer Science Idea: An Example Idea
Powerful computer science concepts appear like this.

A Problem and Its Solution: The Problem that We're Solving
We use data structures to solve problems in modeling the world. In these side bars, we explicitly identify the problem and its solution.

Common Bug: An Example Common Bug
Common things that can cause your recipe to fail appear like this.

Debugging Tip: An Example Debugging Tip
If there's a good way to keep those bugs from creeping into your recipes in the first place, they're highlighted here.

Making It Work Tip: An Example How To Make It Work
Best practices or techniques that really help are highlighted like this.

Acknowledgements

My sincere thanks go out to the following:

- The National Science Foundation who gave us the initial grants that started the Media Computation project;
- Robert "Corky" Cartwright and the whole DrJava development team at Rice University;

- Andrew Sorensen and Andrew Brown, the developers of JMusic;
- Finally but most importantly, Barbara Ericson, and Matthew, Katherine, and Jennifer Guzdial, who allowed themselves to be photographed and recorded for Daddy's media project.

Part I

Introduction to Java: Object-Oriented Programming for Modeling the World

1 Objects for Modeling the World

In the 1994 Disney animated movie *The Lion King*, there is a scene when wildebeests charge over the ridge and stampede the lion king, Mufasa (Figure 1.1[1]). Later, in the 1996 Disney animated movie *The Hunchback of Notre Dame*, Parisian villagers mill about, with a decidedly different look than the rest of the characters (see bottom of Figure 1.2[2]). These are actually related scenes. The wildebeests' stampede was one of the rare times that Disney broke away from their traditional hand-drawn cel animation. The wildebeests were not drawn by hand at all—rather, they were *modeled* and then brought to life in a *simulation*.

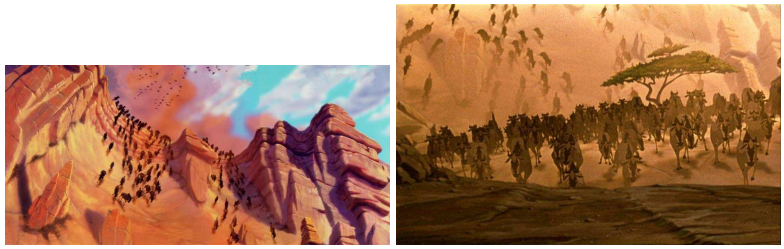

Figure 1.1: Wildebeests in *The Lion King*

A model is a detailed description of structure and behavior. The model of the wildebeests for *The Lion King* described what wildebeests looked like, how they moved, and what they did in a stampede. The villagers' model described what they did when milling about and how they reacted as a group to something noteworthy, like the entrance of Quasimodo. A simulation is execution of the model—simply let the wildebeests start responding to one another and to the obstacles on the ridge, according to the behavior defined in their model. Then, in a sense, simply "film" the screen.

This is a different process than when Pixar created *Toy Story*. There is a model for Woody, which describes how Woody looks and what parts of him move together when he smiles or walks. But *Toy Story* wasn't a

Figure 1.2: Parisian villagers in *The Hunchback of Notre Dame*

simulation. The movements and character responses of *Toy Story* were carefully scripted. In the wildebeest or villagers simulations, each character is simply following a set of rules, usually with some random element (e.g., Should the wildebeest move left or right when coming up against the rock? When should the villagers shuffle or look right?) If you run a simulation a second time, depending on the model and the random variables you used, you may get a different result than you did the first time.

This book is about understanding these situations. The driving questions of this book are ***"How did the wildebeests stampede over the ridge? How did the villagers move and wave?"***. The process of answering those questions will require us to cover a lot of important computer science concepts, like how to choose different kinds of *data structures* to model different kinds of structures, and how to define behavior and even combine structure and behavior in a single model. We will also develop a powerful set of tools and concepts that will help us understand how to use modelling and simulation to answer important questions in history or business.

1.1 Making Representations of the World

What we're doing when we model is to construct a representation of the world. Think about our job as being the job of an artist–specifically, let's consider a painter. Our canvas and paints are what we make our world out of. That's what we'll be using *Java* for.

Is there more than one way to model the world? Can you imagine two different paintings, perhaps *radically* different paintings, of the same thing? Part of what we have to do is to pick the software structures that best represents the structure and behavior that we want to model. Making those choices is solving a *representation problem*.

You already know about mathematics as a way to model the world,

though you may not have thought about it that way. An equation like $F = ma$ is saying something about how the world works. It says that the amount of force (F) in a collision (for example) is equal to the amount of mass (m) of the moving object times its acceleration (a). You might be able to imagine a world where that's not true–perhaps a cartoon world where a slow-moving punch packs a huge wallop. In that world, you'd want to use a different equation for force F.

The powerful thing about software representations is that they are executable–they have *behavior*. They can move, speak, and take action within the simulation that we can interpret as complex behavior, such as traversing a scene and accessing resources. A computer model, then, has a *structure* to it (the pieces of the model and how they relate) and a *behavior* to it (the actions of these pieces and how they interact).

Are there better and worse *physical structures*? Sure, but it depends on what you're going to use them for. A skyscraper and a duplex home each organize space differently. You probably don't want a skyscraper for a nuclear family with 2.5 children, and you're not going to fit the headquarters of a large multinational corporation into a duplex. Consider how different the physical space of a tree is from a snail—each has its own strengths for the contexts in which they're embedded.

Are there better and worse information structures, *data structures*? Imagine that you have a representation that lists all the people in your department, some 50–100 of them sorted by last names. Now imagine that you have a list of all the people in your work or academic department, but grouped by role, e.g., teachers vs. writers vs. administrative staff vs. artists vs. management, or whatever the roles are in your department. Which representation is *better*? Depends on what you're going to do with it.

- If you need to look up the phone number of someone whose name you know, the first representation is probably better.
- If the artistic staff gets a new person, the second representation makes it easier to write the new person's name in at the right place.

Computer Science Idea: Better or worse structures depend on use

A structure is better or worse depending on how it's going to be used – both for access (looking things up) and for change. How will the structure be changed in the future? The best structures are fast to use and easy to change in the ways that you need them to change.

Structuring our data is *not* something new that appeared when we started using computers. There are lots of examples of data structuring and the use of representations in your daily life.

- Consider the stock listing tables that appear in your paper. For each stock (arranged vertically into rows), there is information such as the closing price and the difference from the day before (in columns). A *table* appears in the computer as a *matrix*.

- My daughter, Katie, likes to create treasure hunts for the family, where she hides notes in various rooms (Figure 1.3). Each note references the next note in the list. This is an example of a *linked list*. Each note is a link in a chain, where the note tells you (links to) the next link in the chain. Think about some of the advantages of this structure: the pieces define a single structure, even though each piece is physically separate from the others; and changing the order of the notes or inserting a new note only requires changing the neighbor lists (the ones before or after the notes affected).

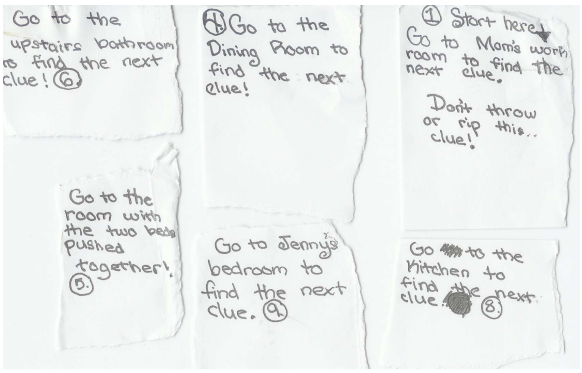

Figure 1.3: Katie's list of treasure hunt clues

- An organization chart (Figure 1.4) describes the relationships between roles in an organization. It's just a representation–there aren't really lines extending from the feet of the CEO into the heads of the Presidents of a company. This particular representation is quite common–it's called a *tree*. It's a common structure for representing *hierarchy*.

- A map (Figure 1.5) is another common representation that we use. The real town actually doesn't look like that map. The real streets have other buildings and things on them–they're wonderfully rich and complex. When you're trying to get around in the town, you don't want a satellite picture of the town. That's too much detail. What you really want is an *abstraction* of the real town, one that just shows you what you need to know to get from one place to another. We think about Interstate I-75 passing through Atlanta, Chattanooga, Knoxville, Cincinnati, Toledo, and Detroit, and Interstate I-94 goes

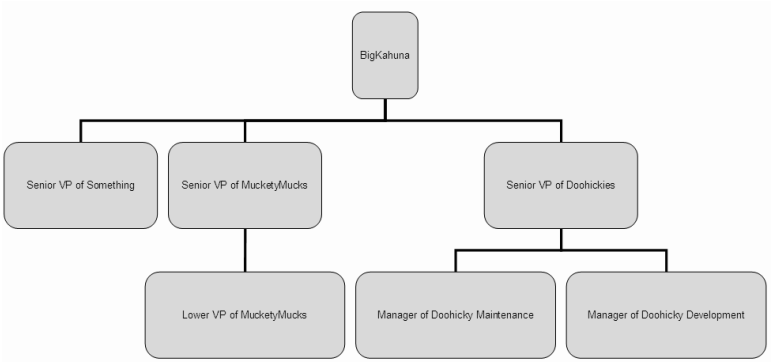

Figure 1.4: An organization chart

from Detroit through Chicago. We can think about a map as *edges* or *connections* (streets) between points (or *nodes*) that might be cities, intersections, buildings, or places of interest. This kind of a structure is called a *graph*.

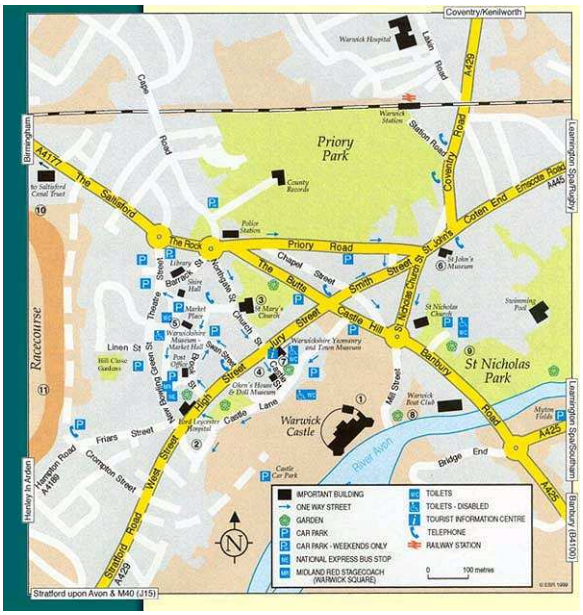

Figure 1.5: A map of a town

Each of these data structures have particular *properties* that make

them good for some purposes and bad for others. A table or matrix is really easy for looking things up (especially if it's ordered in some way). But if you have to insert something into the middle of the table, everything else has to move down. When we're talking about space in the computer (*memory*), we're literally talking about moving each element in memory separately. On the other hand, inserting a new element into a linked list or into a graph is easy—just add edges in the right places.

How does it matter what kind of structure that you're using? It matters because of the way that computer memory works. Remember that you can think of memory as being a whole bunch of mailboxes in a row, each with its own address. Each mailbox stores exactly one thing. In reality, that one thing is a binary pattern, but we can interpret it any way we want, depending on the encoding. Maybe it's a number or maybe it's a character.

A table (a matrix or an array) is stored in consecutive mailboxes. So, if you have to put something into the middle of a table, you have to move the things already in there somewhere else. If you put something new where something old used to be, you end up over-writing the something old.

To make it clear, let's imagine that we have a table that looks something like this:

Name	**Age**	**Weight**
Arnold	12	220
Kermit	47	3
Ms. Piggy	42	54

Let's say that we want to add "Fozzie" to the list, who's 38 and weighs 125 pounds. He would go below Arnold and above Kermit, but if just put him after Arnold, we would over-write Kermit. So, the first thing we have to do is to make room for Fozzie at the *bottom* of the table. (We can simply annex the next few mailboxes after the table.)

Name	**Age**	**Weight**
Arnold	12	220
Kermit	47	3
Ms. Piggy	42	54

Now we have to copy everything down into the new space, opening up a spot for Fozzie. We move Ms. Piggy and her values into the bottom space, then Kermit into the space where Ms. Piggy was. That's two *sets* of data that we have to change, with three values in each set.

Notice that that leaves us with Kermit's data duplicated. That's okay—we're about to overwrite them.

Name	**Age**	**Weight**
Arnold	12	220
Fozzie	38	125
Kermit	47	3
Ms. Piggy	42	54

Now let's compare that to a different structure, one that's like the treasure trail of notes that Katie created. We call that a linked list representation. Consider a note (found in a bedroom) like:

"The next note is in the room where we prepare food."

Let's think about that as a note *in* the bedroom that *references* (says to *go to*) the kitchen. We'll draw that like this:

bedroom kitchen

In terms of memory mailboxes, think about each note as having two parts: a current location, and where *next* is. Each note would be represented as two memory mailboxes—something like this:

Current location:	Where to go next:
Bedroom	Kitchen

So let's imagine that Katie has set up a trail that looks like this:

Katie's bedroom

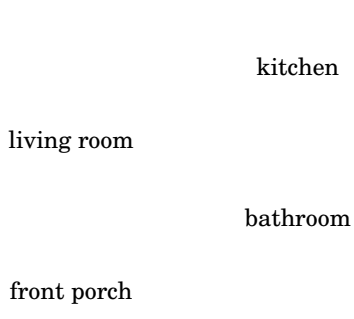
kitchen

living room

bathroom

front porch

Now, she changes her mind. Katie's bedroom shouldn't refer to the kitchen; her bedroom should point to Matthew's bedroom. How do we change that? Unlike the table, we don't have to move any data anywhere. We simply make Matthew's bedroom (anywhere), then point Katie's bedroom's note to Matthew's bedroom, and point Matthew's bedroom's note to the kitchen (where Katie's bedroom used to point).



In terms of memory mailboxes, we only changed the *next* part of Katie's bedroom note, and the location and next parts of the (new) Matthew's bedroom note. No copying of data was necessary.

Adding to a linked list representation is much easier than adding to a table, especially when you're adding to the middle of the table. But there are advantages to tables, too. They can be faster for looking up particular pieces of information.

Much of this book is about these trade-offs between different data structures. Each data structure has strengths that solve some sets of problems, but the same data structure probably has weaknesses in other areas. Each choice of data structure is a trade-off between these strengths and weaknesses, and the choices can only be made in the context of a particular problem.

These data structures have a *lot* to do with our wildebeests and villagers.

- The visual structure of villagers and wildebeests (e.g., how legs and arms attach to bodies) is typically described as a tree or graph.
- Tracking which villager is next to do something (e.g., move around) is a queue.
- Tracking all of the wildebeests to stampede is often done in a *list* (like a linked list).
- The images to be used in making the villagers wave or wildebeests run are usually stored in a list.

1.2 Why Java?

Why is this class taught in Java?

- Overall, Java is faster than Python (and definitely faster than Jython). We can do more complex things faster in Java than in Python.

- Java is a good language for exploring and learning about data structures. It makes it explicit how you're connecting data through *references*.
- More computer science classes are taught in Java than Python. So if you go on beyond this class in data structures, knowing Java is important.
- Java has "resume-value." It's a well-known language, so it's worth it to be able to say, even to people who don't really know computer science, that you know Java. This is important—you'll learn the content better if you have good reason for learning it.

Getting Java Set-Up

You can start out with Java by simply downloading a *JDK* (*Java Development Kit*) from `http://www.java.sun.com` for your computer. With that, you have enough to get started programming Java. However, that's not the easiest way to *learn* Java. In this book, we use *DrJava* which is a useful *IDE* (*Integrated Development Environment*)—a program that combines facilities for editing, compiling, debugging, and running programs. DrJava is excellent for learning Java because it provides an Interactions Pane where you can simply type in Java code and try it out. No files or compilers necessary to get started.

If you'd like to use DrJava, follow these steps:

- Download and install DrJava from `http://www.drjava.org`.
- Download and install *JMusic* from `http://jmusic.ci.qut.edu.au/`.
- You'll need to tell DrJava about JMusic in order to access it. You use the Preferences in DrJava (see Figure 1.6) to add in the JMusic *jar file* and the instruments (Figure 1.7).
- Make sure that you grab the `MediaSources` and `java-source` from the CD or the website.
- Just as you added JMusic to your DrJava preferences, add the `java-source` folder to your preferences, too.

Making It Work Tip: Keep all your Java files in your `java-source` directory

Once you put `java-source` in your Preferences, you will have added it to Java's *classpath*. That means that everything you create will be immediately accessible and easy to build upon. (Figure 1.8).

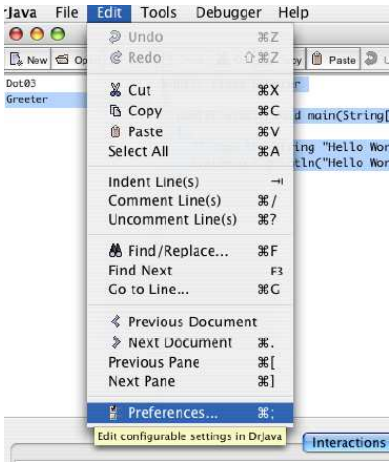


Figure 1.6: Opening the DrJava Preferences

Figure 1.7: Adding the JMusic libraries to DrJava in Preferences

* * *

Once you start DrJava, you'll have a screen that looks like Figure 1.9.

If you choose *not* to use DrJava, that's fine. Set up your IDE as best you wish, but be sure to install JMusic and set up your classpath to access JMusic and `java-source` directory. This book will assume that you're using DrJava and will describe using classes from the Interactions Pane, but you can easily create a class with a `main` method (as we'll start talking

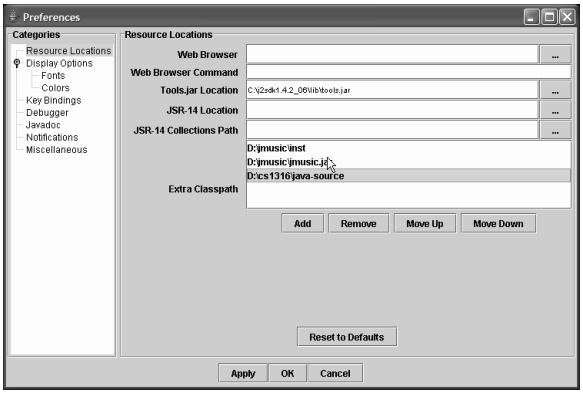

Figure 1.8: Adding `java-source` to DrJava

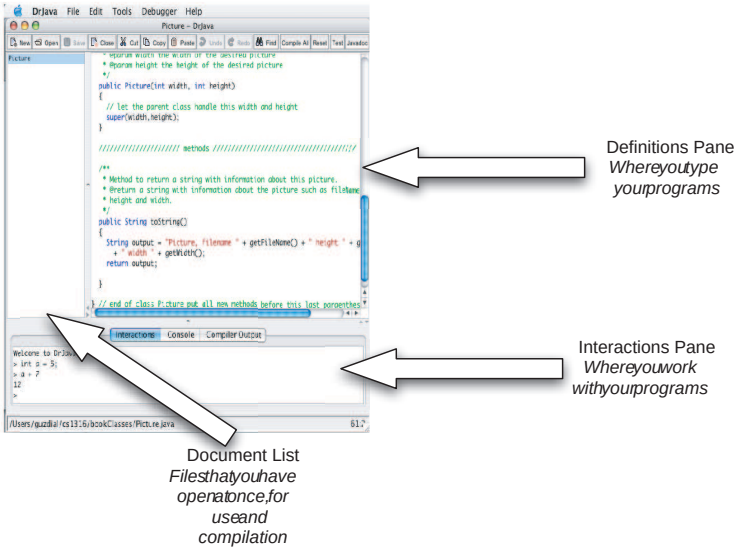

Figure 1.9: Parts of DrJava window

2 Introduction to Java

Chapter Learning Objectives

- Introducing Java with an explanation of why it's relevant to modelling and simulation.
- Brief taste of media manipulation of pictures, sounds, and music.

2.1 What's Java about?

Nearly everything in Java is an *object*. In *object-oriented programming*, the programmer cares about more than just *specifying* a process. In other languages, like Python or Visual Basic, you mostly tell the computer "First you do this, then you do that." In object-oriented programming (which you have to do in Java, since it's almost all objects), you care about who (or what) does the process, and how the overall process *emerges* from the interaction of different objects. The software engineering term for this is *responsibility-driven design*—we don't just care about how the process happens, we care about who (which object) does which part of the process.

Object-oriented programming dates back to a programming language called *Simula*, which was a programming language for creating simulations of the world. The idea was to describe the world that you cared about in the Simula language, e.g. how customers worked their way through a store floor, how material flowed through a factory, how deer and wolves balanced each other ecologically in the ecosystem. That description is called a *model*. When Alan Kay discovered Simula in the late 1960's, he realized that all programs can be thought of as modelling some world (real or imaginary) and all programming is about simulation. It was that insight that led to his programming language *Smalltalk* and our current understanding of object-oriented programming, which is what leads us to Java.

Thinking about programming as modelling and simulation means that you have to do this responsibility-driven design—you have to share control over what happens in the overall process across many objects. That's the way that the real world works. Setting aside theological arguments, there is no great big **for** loop telling everything in the real world to take another time step. You don't write one big master program in Java—your program arises out of the interaction of lots of objects, just like the real world. Most

importantly, in the real world, no *one* object **knows** everything and can **do** everything. Instead, in the real world and in Java, each object has things that it *knows* and things that it can *do* (or knows how to do).

2.2 Basic (Syntax) Rules of Java

Here are the basic rules for doing things in Java. We'll not say much about classes and methods here–we'll introduce the syntax for those as we need them. These are the things that you've probably already seen in other languages.

Declarations and Types

If your past experience programming was in a language like Python, Visual Basic, or Scheme, the trickiest part of learning Java will probably be its *types*. All variables and values (including what you get back from *functions*–except that there are no functions, only *methods*) are typed. We must declare the type of a variable before we use it. The types Picture, Sound, and Sample are already created in the base classes for this course for you. Other types are built-in for Java.

Many of these types are actually the names of classes names. A class specifies what all the objects of that class *know* and can *do*. The Picture class specifies what pictures can do (e.g., show() themselves) and what they know (e.g., they know their pixels). We *declare* variables to only hold objects of particular classes.

Java, unlike those other languages, is *compiled*. The Java compiler actually takes your Java program code and turns it into another program in another language–something close to *machine language*, the bytes that the computer understands natively. It does that to make the program run faster and more efficiently.

Part of that efficiency is making it run in as little memory as possible–as few bytes, or to use a popular metaphor for memory, mailboxes. If the compiler knows just how many bytes each variable will need, it can make sure that everything runs as tightly packed into memory as possible. How will the compiler know which variables are integers and which are floating point numbers and which are pictures and which are sounds? We'll tell it by *declaring* the type of the variable.

```
> int a = 5;
> a + 7
12
```

In the below java, we'll see that we can only declare a variable once, and a floating point number must have an "f" after it.

```
> float f;
> f = 13.2;
```

```
Error: Bad types in assignment
> float f = 13.2f;
Error: Redefinition of 'f'
> f = 13.2f
13.2
```

The type **double** is also a floating point number, but doesn't require anything special.

```
> double d;
> d = 13.231;
> d
13.231
> d + f
26.43099980926514
```

There are strings, too.

```
> String s = "This is a test";
> s
"This is a test"
```

Assignment

```
VARIABLE = EXPRESSION
```

The equals sign (=) is assignment. The left VARIABLE should be replaced with a declared variable, or (if this is the first time you're using the variable) you can declare it in the same assignment, e.g., **int** a = 12;. If you want to create an object (not a *literal* like the numbers and strings in the last section, you use the term **new** with the name of the class (maybe with an input for use in constructing the object).

```
> Picture p = new Picture(FileChooser.pickAFile());
> p.show();
```

All statements are separated by semi-colons. If you have only one statement in a *block* (the body of a conditional or a loop or a method), you don't have to end the statement with a semi-colon.

Conditionals

```
if (EXPRESSION)
   STATEMENT
```

An expression in Java is pretty similar to a logical expression in any other language. One difference is that a logical *and* is written as &&, and an *or* is written as ||.

STATEMENT above can be replaced with a single statement (like a=12;) or it can be *any number* of statements set up inside of *curly braces*–{ and }.

```
if (EXPRESSION)
   THEN-STATEMENT
else
   ELSE-STATEMENT
```

Iteration

```
while (EXPRESSION)
   STATEMENT
```

There is a **break** statement for ending loops.

Probably the most confusing iteration structure in Java is the **for** loop. It really combines a specialized form of a **while** loop into a single statement.

```
for (INITIAL-EXPRESSION ; CONTINUING-CONDITION;
ITERATION-EXPRESSION)
   STATEMENT
```

A concrete example will help to make this structure make sense.

```
> for (int num = 1 ; num <= 10 ; num = num + 1)
       System.out.println(num);
1
2
3
4
5
6
7
8
9
10
```

The first thing that gets executed *before anything inside the loop* is the INITIAL-EXPRESSION. In our example, we're creating an integer variable num and setting it equal to 1. We'll then execute the loop, testing the CONTINUING-CONDITION before each time through the loop. In our example, we keep going as long as the variable num is less than or equal to 10. Finally, there's something that happens *after* each time through the loop – the ITERATION-EXPRESSION. In this example, we add one to num. The result is that we print out (using System.out.println, which is the same as print in many languages) the numbers 1 through 10. The expressions in the **for** loop can actually be several statements, separated by commas.

The phrase VARIABLE = VARIABLE + 1 is so common in Java that a short form has been created.

```
> for (int num = 1 ; num <= 10 ; num++)
       System.out.println(num);
```

Arrays

To declare an array, you specify the *type* of the elements of the array, then open and close *square brackets*. (In Java. all elements of an array have the same type.) Picture [] declares an array of type Picture. So Picture [] myarray; declares myarray to be a variable that can hold an array of Pictures.

To actually create the array, we might say something like **new** Picture[5]. This declares an array of five pictures. This does *not* create the pictures, though! Each of those have to be created separately. The indices will be 0 to 4 in this example. Java indices start with zero, so if an array has five elements, the maximum index is four. The fifth array reference (as seen below) will result in an error–the frequently visited ArrayIndexOutOfBoundException.

```
> Picture [] myarray = new Picture[5];
> Picture background = new Picture(800,800);
> FileChooser.setMediaPath("D:/cs1316/mediasources/");
> //Can load in any order
> myarray[1]=new Picture(FileChooser.getMediaPath("jungle.jpg"));
> myarray[0]=new Picture(FileChooser.getMediaPath("katie.jpg"));
> myarray[2]=new Picture(FileChooser.getMediaPath("barbara.jpg"));
> myarray[3]=new Picture(FileChooser.getMediaPath("flower1.jpg"));
> myarray[4]=new Picture(FileChooser.getMediaPath("flower2.jpg"));
> myarray[5]=new Picture(FileChooser.getMediaPath("butterfly.jpg"));
ArrayIndexOutOfBoundsException:
  at java.lang.reflect.Array.get(Native Method)
```

Strings

A *string* is not strictly an array, but it is similar to one. You can create a string from an array of characters. Characters are defined with single quotes (e.g., 'a') as opposed to double quotes (e.g., "a") which define strings.

```
> char characters[]={'B','a','r','b'}
> characters
[C@1ca209e
> String wife = new String(characters)
> wife
"Barb"
```

You cannot index a string with square brackets like an array. You can use the substring method on a string to retrieve individual characters (*substrings*) within the string. The substring method takes a starting and ending position in the string, starting with zero.

```
> String name = "Mark Guzdial";
> name
"Mark Guzdial"
> name[0]
```

```
Error: 'java.lang.String' is not an array
> name.substring(0,0)
""
> name.substring(0,1)
"M"
> name.substring(1,1)
""
> name.substring(1,2)
"a"
```

2.3 Using Java to Model the World

We have talked about the value of objects in modelling the world, and about the value of Java. In this section, we use Java to model some objects from our world. Let's consider the world of a student.

A Problem and Its Solution: What should I model?

When you model something in the world (real or virtual) as an object, you are asking yourself "What's important about the thing that I am trying to model?" Typically, that question is answered by considering what you want from the model. Why are you doing this model? What's important about it? What questions are you trying to answer?

If you are creating a model of students, then the question that you want to answer determines what you model and how you model it. If you want to create a model in order to create a course registration system, then you care about the students as people with a particular role. If you wanted to model students to answer questions about their health (e.g., how dormitory food impacts their liver, or how lack of sleep impacts their brains), then you want to model students as biological organisms with organs like livers.

For our purposes in this chapter, let's imagine that we are modeling students in order to explore registration behavior. Given the previous, that means that we care about students as people. At the very least then, we want to define a class Student and a class Person.

A Problem and Its Solution: How much should I model?

Always try for the minimal model. Model as little as possible to answer your question. Models grow in complexity rapidly. The more attribtues and variables that you model, the more that you have to worry about later. When you model, you are always asking yourself "Did I deal with all the relationships between all the variables in this model?" The more variables you model, the more relationships there are to consider. Model as little as

you need to answer your question.

We are going to define the class Student as a *subclass* of Person. There are several implications of that statement.

- Class Person is a *superclass* of Student.
- We also say that Person is the *parent class* of Student, and Student is the *child class* of Person.
- All *fields* or *instance variables* of the class Person are automatically in instances of the class Student. That does not mean that all those variables are accessible—some of them may be *private* which means that they are defined in the parent class, they are accessible in the parent class, but they are not accessible in the methods of the subclass.
- All *methods* in the superclass, Person are automatically usable in the subclass Student.
- We should be able to think about the subclass, Student, as being "a kind of" (sometimes shortened to *kind-of*) the superclass. A student is a kind of person—that's true, so it's a reasonable superclass-subclass relationship to set up.

Here's an initial definition of the class Person.

Example Java Code: **Person class, starting place** *Program Example #1*

```
public class Person {
  public String name;
}
```

That's enough to create an instance of class Person and use it. Here's how it will look in DrJava:

```
> Person fred = new Person();
> fred.name
null
> fred.name = "Fred";
> fred.name
"Fred"
```

There's an implication of this implementation of Person—we can change the name of the person. Should we be able to do this?

```
> fred.name = "Mabel";
> fred.name
"Mabel"
```

If we want to control name changes, we can make the field name private. To change or get the name, we can use *accessor* methods (sometimes called *getter* and *setter* methods because they let us get and set instance variabls). These methods could check whether it's appropriate to set (or get) the variable.

Program Example #2

Example Java Code: **Person, with a private name**

```
public class Person {
  private String name;

  public void setName(String somename)
  {this.name = somename;}

  public String getName()
  {return this.name;}
}
```

How it works: The field name is now **private** meaning that only methods in this class can directly manipulate this variable. The method setName takes a String as input, then sets the name to that input. Since setName doesn't return any value, it's return value is **void**—literally, nothing. The method getName does return the value of the variable name so it has a return value of String. Notice that both of these methods refer to **this**.name. This is a special variable meaning the object that has been told to getName or setName. The phrase **this**.name means "The variable name that is within the object **this**, the one that was told to execute this method."

Now, we manipulate the field name using these methods—because we can't access the variable directly anymore. Within getName and setName in this example, the variable **this** means fred — they are two variable names referencing the exact same object.

```
> Person fred = new Person();
> fred.setName("Fred");
> fred.getName()
"Fred"
```

This works well for getting and setting the name. Let's consider what happens when we first create a new Person instance.

```
> Person barney = new Person();
> barney.getName()
null
```

Should "barney" have a **null** name? The value **null** means that this variable does not yet have a value. How do we define an instance of Person such that it automatically has a value for its name? That would be the way that the real world works, that baby people get names at birth.

We can make that happen by defining a *constructor*. A constructor is a method that gets called when a new instance is created. A constructor has the same name as the class itself. It can take an input, so that we can create an object with certain values. Constructors don't *have* to take inputs—it's okay to just create an instance and have pre-defined values for variables.

Example Java Code: **Person, with constructors** *Program Example #3*

```
public class Person {
  private String name;

  public Person(){
    this.setName("Not-yet-named");
  }

  public Person(String name){
    this.setName(name);
  }
  public void setName(String somename)
  {this.name = somename;}

  public String getName()
  {return this.name;}
}
```

How it works: This version of class Person has two different constructors. One of them takes no inputs, and gives the name field a predefined, default value. The other takes one input—a new name to be given to the new object. It's okay to have multiple constructors as long as they can be distinguished by the inputs. Since one of these takes nothing as input, and the other takes a String, it's pretty clear which one we're calling when.

```
> Person barney = new Person("Barney")
// Here, we call the constructor that takes a string.
> barney.getName()
"Barney"
```

```
> Person wilma = new Person()
// Here, we call the constructor that doesn't take an input
> wilma.getName()
"Not-yet-named"
> wilma.setName("Wilma")
> wilma.getName()
"Wilma"
```

If we give Java some inputs to the constructor, but those inputs don't match any existing constructor, we get an error.

```
> Person agent99 = new Person(99)
java.lang.NoSuchMethodException: Person constructor
```

Discourse Rules for Java

In an American "Western" novel or movie, there are certain expectations. The hero carries a gun and rides a horse. The hero never uses a bazooka, and never flies on a unicorn. Yes, you can make a Western that has a hero with a bazooka or a unicorn, but it's considered a weird Western—you've broken some rules.

Those are *discourse rules*—the rules about how we interact in a certain genre or setting. They are not laws or rules that are enforced by some outside entity. They are about expectations.

There are discourse rules in all programming languages. Here are some for Java:

- Class names start with capital letters. All regular variables and method names start with lowercase letters. There are a couple special cases of variables (those that belong to a class, and those that are constant or **final**) that are also capitalized—those are rather rare.
- Class names are never plurals. If you want more than one instance of a class, you use an array or a list. The class name is not plural.
- Class names are typically nouns, not verbs.
- Instance variables and methods always start with lowercase letters.
- Methods should describe verbs–what objects know how to do.
- Accessors are typically named "set-" and "get-" the name of the field. To separate the word "set" or "set" from the variable name, the first letter of the variable name is capitalized.

Defining toString

What is an instance of Person? What do we get if we try to print its value?

```
> Person barney = new Person("Barney")
> barney
Person@63a721
```

That looks like Barney is a Person followed by some expletive or code. We can make the display of Barney look a little more reasonable using the method toString. When we try to print an object (by simply displaying its value in the Interactions Pane in DrJava, or when printed from a program using System.out.println), the object is converted to a string. The method toString does that conversion. By providing a good toString method, we can make debugging easier—we can simply print the variable at important points in the code to see what the object's important values are.

Example Java Code: **toString method for Person** *Program Example #4*

```
public String toString(){
    return "Person named "+this.name;
  }
```

How it works: The method toString returns a String, so we declare the return type of toString to be String. We can stick the words "Person named" before the actual name using the + operator—we call that *string concatenation*.

Now, we can immediately print Barney after creating him, and his value is reasonable and useful.

```
> Person barney = new Person("Barney")
> barney
Person named Barney
```

Defining Student as subclass of Person

Now, let's define our class Student. A student is a kind of person—we established that earlier. In Java, we say that Student **extends** Person—that means that Student is a subclass of Person. It means that a Student is everything that a Person is, with an extension in some way.

How should Student instances be different? Let's say that a Student has an identification number. That's not particularly insightful, but it is likely true.

Example Java Code: **Student class, initial version** *Program Example #5*

```
public class Student extends Person {
  private int idnum;

  public int getID(){ return idnum;}
  public void setID(int id) {idnum = id;}
}
```

How it works: Assuming that the identification number, idnum, will fit within the bounds of an integer **int**, this isn't a bad way to go. If the ID number might be too large, or if we would want to record dashes or spaces within it, using an **int** would be a bad model for the real identification number. Notice that we are also creating a getter and a setter for idnum.

From here, we can create instances of Student, but only by name—an inherited constructor from Person. There is no method Student(), so we can't create an instance without any input yet.

```
> Student betsy=new Student("Betsy")
java.lang.NoSuchMethodException: Student constructor
> Student betsy = new Student()
> betsy.getName()
"Not-yet-named"
> betsy.setName("Betsy")
> betsy.getName()
"Betsy"
> betsy.setID(999)
> betsy.getID()
999
```

If we print out Betsy, she'll tell us that she's a Person, not a Student. That's because the class Student inherits the toString method from Person.

```
> betsy
Person named Betsy
```

Let's define the class Student with reasonable constructors.

Program Example #6

Example Java Code: **Class Student, with constructors**

```
public class Student extends Person {
  private int idnum;

  // Constructors
  public Student(){
    super(); //Call the parent's constructor
   idnum = -1;
   }
```

```
  public Student(String name){
    super(name);
    idnum = -1;
  }
  public int getID(){ return idnum;}
  public void setID(int id) {idnum = id;}
}
```

How it works: We create a default value for the idnum as -1. We also create accessors, getID() and setID(), for manipulating the identification number. Note that we still want to do whatever the Person constructors would do, so we call them with **super**.

Debugging Tip: Make the call to super *first* in a method
If you want to extend a method from a superclass, call **super** first. Let the superclass do whatever it would do. Then, extend the superclass's version with what you want the subclass to do.

Creating a main() method

How do we test our Java code? For those of us using DrJava[1], it's easy—we can simply type code in the Interactions Pane. What if you don't *have* an Interactions Pane? Then, you can test code by providing a main() method. There can be at most one main method in a class. It is often used to try out the class.

A main method is declared as **public static void** main(String[] args), which is a real mouthful. That means (in brief—there is a better explanation later in the book):

- **public** means that this method can be accessed by any other class.
- **static** means that this method is known to the *class*, not just the instances. We can execute it without any instances having been created.
- **void** means that this method does not return anything.
- String[] args means that this method *could* be executed by running it from a command line, and any words on that line (e.g., filenames or options) would be passed on to the main method as elements in an array of strings named args (for "arguments").

[1] Or BlueJ, http://www.bluej.org

Program Example #7

Example Java Code: **main() method for Person**

```
public static void main(String [] args){
   Person fred = new Person("Fred");
   Person barney = new Person("Barney");

   System.out.println("Fred is "+fred);
   System.out.println("Barney is "+barney);
 }
```

How it works: When this method is in the class Person, and we `run` the class (however your Java environment allows you to do this) or execute it from the command line, this method is executed. Two instances of class Person are created, and then both are printed to the console (or Interactions Pane, for DrJava). System.out.println prints the input to the console. When what is to be printed includes objects, like fred and barney above, they are converted to the type String (using the object's toString method) and displayed to the console.

When we execute this using the RUN button, we see:

```
Welcome to DrJava.
> java Person
Fred is Person named Fred
Barney is Person named Barney
```

Exploring Inheritance

A subclass inherits all the methods in the superclass—*unless* the subclass overrides it. If the subclass defines its own version of a method in the superclass, then the subclass version will be executed from an instance of the subclass. (An instance of the superclass will, of course, still execute the method of the superclass.)

Let's add a method to class Person that allows instances of Person to be friendly and greet people.

Program Example #8

Example Java Code: **greet method for Person**

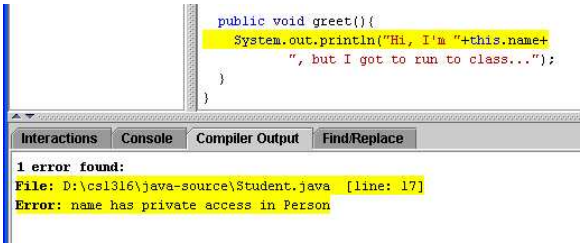
```
public void greet(){
   System.out.println("Hi! I am "+this.name);
 }
```

Executing this method looks like this:

```
> Person bruce = new Person("Bruce")
> bruce.greet()
Hi! I am Bruce
> Person george = new Person("George W.")
> george.greet()
Hi! I am George W.
> Student krista = new Student("Krista")
> krista.greet()
Hi! I am Krista
```

Let's imagine that we create a greet method for class Student, too. We might try something like this:

```
public void greet(){
    System.out.println("Hi! I'm "+this.name+
        " but I got to run to class...");
  }
```



Unfortunately, that will generate an error:

That error occurred because name is a **private** variable. The subclass, Student can't access the variable. Only the class that defined it, Person can access it. Instances of the class Student certainly *have* an name variable—they just can't access it directly. If we want to access the variable in Student, we have to use the accessors.

Example Java Code: **greet method for Student**

Program Example #9

```
public void greet(){
    System.out.println("Hi, I'm "+this.getName()+
        ", but I got to run to class...");
  }
```

Now we get different effects when we ask a Person or Student to greet().

```
Welcome to DrJava.
> Person george = new Person("George W.")
```

```
> george.greet()
Hi! I am George W.
> Student krista = new Student("Krista")
> krista.greet()
Hi, I'm Krista, but I got to run to class...
```

It's worth thinking this through—what exactly happened when we executed krista.greet()?

- Krista knows that she is a Student—an instance of the class Student. Krista knows that if she can't greet, she can ask her parent to do it for her.
- She does know how to greet(), so she executes that method.
- But midway, "Uh-oh. I dont know how to getName()!" So Krista asks her parent (who might have asked his parent, and so on, as necessary), who does know how to getName().

Let's try one more experiment:

```
> Person fred = new Student("Fred")
> Student mabel = new Person("Mabel")
ClassCastException: mabel
```

Why did the first statement work, but the second one generated an error? Variables in Java always have a particular *type*. They can hold values that match that type. A Person variable fred can hold a Person instance. A variable of a given type can also hold instances of any *subclasses*. Thus, Person variable fred can hold an instance of class Student. However, a variable of a given type can *not* hold instances of any *superclasses*. Thus, the Student variable mabel cannot hold an instance of the class Person.

There are some subtle implications of putting an object of one type in a variable of another type. Consider the following example:

```
> fred.greet()
Hi, I'm Fred, but I got to run to class...
> fred.setID(999)
Error: No setID' method in 'Person'
> ((Student) fred).setID(999)
> ((Student) fred).getID()
999
```

Our Person variable fred knows how to greet()—of course it does, since both Person and Student classes know how to greet. Note that fred executes the *Student* method greet()—that also makes sense, since fred contains an instance of the class Student.

Here's the tricky part: fred can't setID(). You may be thinking, "But Fred's a Student! Students know how to set their ID!" Yes, that's true. The variable fred, though, is declared to be type Person. That means that Java is

checking that fred is only asked to do things that a Person might be asked to do. A Person does now know how to set its ID. We can tell Java, "It's okay—fred contains a Student" by *casting*. When we say ((Student) fred), we are telling Java to treat fred like a Student and let it execute Student methods. Then it works.

2.4 Manipulating Pictures in Java

We can get *file paths* using FileChooser and its method pickAFile(). FileChooser is a **class** in Java. The method pickAFile() is special in that it's known to the class, not to objects created from that class (*instances*). It's called a **static** or *class method*. To access that method in that class, we use *dot notation*: *Classname.methodname()*.

```
> FileChooser.pickAFile()
"/Users/guzdial/cs1316/MediaSources/beach-smaller.jpg"
```

In the array example at the end of the last section, we see the use of FileChooser.setMediaPath and FileChooser.getMediapath. The method setMediaPath takes as input a directory—note that it *must* end in a slash. (You can always use forward slashes here—it'll work right on any platform.) The method getMediaPath takes a filename, then returns the directory concatenated in front of it. So FileChooser.getMediaPath("jungle.jpg") actually returns "D:/cs1316/mediasources/jungle.jpg". *You only need to use setMediaPath once!* It gets stored in a file on your computer, so that all your code that accesses getMediaPath will just work. This makes it easier to move your code around. New pictures don't have any value – they're **null**.

```
> Picture p;
> p
null
```

Debugging Tip: Did you get your Picture?

If you got an error as soon as you typed Picture p; there are two main possibilities.

- All the Java files we provide you are in source form. You need to compile them to use them. Open `Picture.java` and click COMPILE ALL. If you get additional errors about classes not found, open those files and compile them, too.
- You might not have your PREFERENCES set up correctly. If Java cant find Picture, you cant use it.

* * *

Debugging Tip: Semi-colons or not?

In the DrJava Interactions Pane, you don't have to end your lines with a semi-colon (;). If you don't, you're saying to DrJava "Evaluate this, and show me the result." If you do, you're saying "Treat this like a line of code, just as if it were in the Code Pane." Leaving it off is a useful debugging technique—it shows you what Java thinks that variable or expression means. But be careful—you *must* have semi-colons in your Code Pane!

To make a new picture, we use the code (you might guess this one) **new** Picture(). Then we'll have the picture show itself by telling it (using dot notation) to show() (Figure 2.1).

```
> p = new Picture("/Users/guzdial/cs1316/MediaSources/beach-smaller.jpg");
> p
Picture, filename /Users/guzdial/cs1316/MediaSources/beach-smaller.jpg height 360 wi
> p.show()
```

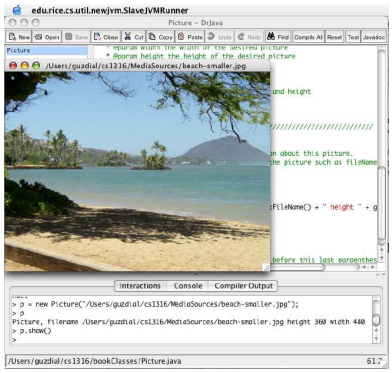


Figure 2.1: Showing a picture

The variable p in this example has the type Picture. That means that it can only hold pictures. We can assign it to new pictures, but we can't assign it to a Sound or an **int**. We also can't re-declare p.

Common Bug: One declaration per scope

Within a given *scope* (e.g., any set of curly braces, such as a single method, or the Interactions Pane in DrJava between compilations or reset), a variable can be declared once and only once. Another declaration is an error.

You can *use* the variable as much as you might like after declaration, but you can only *declare* it once.

After the scope in which it was declared, the variable ceases to exist. So, if you declare a variable inside the curly braces of a **for** or **while** loop, it will not be available *after* the end curly brace.

Common Bug: Java may be hidden on Macintosh

When you open windows or pop-up file choosers on a Macintosh, they will appear in a separate "Java" application. You may have to find it from the Dock to see it.

The downside of types is that, if you need a variable, you need to create it. In general, that's not a big deal. In specific cases, it means that you have to plan ahead. Let's say that you want a variable to be a pixel (class Pixel) that you're going to assign inside a loop to each pixel in a list of pixels. In that case, the declaration of the variable *has* to be *before* the loop. If the declaration were inside the loop, you'd be re-creating the variable, which Java doesn't allow.

To create an array of pixels, we use the notation Pixels []. The square brackets are used in Java to index an array. In this notation, the open-close brackets means "an array of indeterminate size."

Here's an example of increasing the red in each pixel of a picture by doubling (Figure 2.2).

```
> Pixel px;
> int index = 0;
> Pixel [] mypixels = p.getPixels();
> while (index < mypixels.length)
{
     px = mypixels[index];
     px.setRed(px.getRed()*2);
     index = index + 1;
}
> p.show()
```

How would we put this process in a file, something that we could use for *any* picture? If we want *any* picture to be able to increase the amount of red, we need to edit the class Picture in the file `Picture.java` and add a new method, maybe named increaseRed.

Here's what we would want to type in. The special variable **this** will represent the Picture instance that is being asked to increase red. (In Python or Smalltalk, **this** is typically called self.)

Figure 2.2: Doubling the amount of red in a picture

* * *

Program Example #10

Example Java Code: **Method to increase red in Picture**

```
/**
 * Method to increase the red in a picture.
 */
public void increaseRed()
{
  Pixel px;
  int index = 0;
  Pixel [] mypixels = this.getPixels();
  while (index < mypixels.length)
  {
    px = mypixels[index];
    px.setRed(px.getRed()*2);
    index = index + 1;
  }
}
```

How it works:

- The notation /∗ begins a comment in Java – stuff that the compiler will ignore. The notation ∗/ ends the comment.
- We have to declare methods just as we do variables! The term **public** means that anyone can use this method. (Why would we do otherwise? Why would we want a method to be **private**? We'll start explaining that next chapter.) The term **void** means "this is a method

that doesn't return anything–don't expect the return value to have any particular type, then."

Once we type this method into the bottom of class Picture, we can press the COMPILE ALL button. If there are no errors, we can test our new method. When you compile your code, the objects and variables you had in the Interactions Pane disappear. You'll have to recreate the objects you want.

Making It Work Tip: The command history isn't reset!
Though you lose the variables and objects after a compilation, the history of all commands you typed in DrJava is still there. Just hit up-arrow to get to previous commands, then hit return to execute them again.

You can see how this works in Figure 2.3.

```
> Picture p = new Picture(FileChooser.pickAFile());
> p.increaseRed()
> p.show()
```

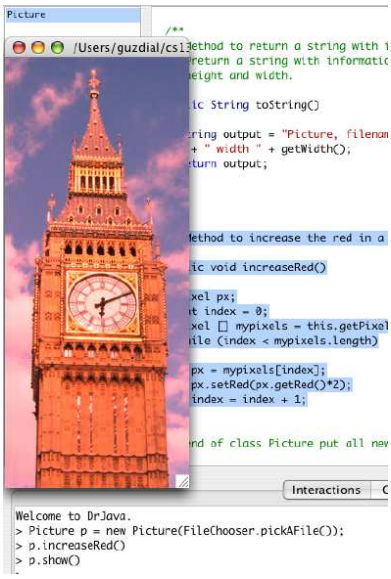

Figure 2.3: Doubling the amount of red using our increaseRed method

Later on, we're going to want to have characters moving to the left or to the right. We'll probably only want to create one of these (left or

right), then flip it for the other side. Let's create the method for doing that. Notice that this method returns a *new* picture, not modifying the original one. Instead of being declared **void**, the flip method is declared Picture. It returns a picture. At the bottom of the method, you'll see that it does actually use **return** to return the target picture that we create inside the method. We'll see later that that's pretty useful, to create a new image rather than change the target picture. (Figure 2.4).

Program Example #11

Example Java Code: **Method to flip an image**

```
/**
 * Method to flip an image left-to-right
 **/
public Picture flip() {

  Pixel currPixel;
  Picture target = new Picture(this.getWidth(),this.getHeight());

  for (int srcx = 0, trgx = getWidth()-1; srcx < getWidth();
        srcx++, trgx--)
  {
    for (int srcy = 0, trgy = 0; srcy < getHeight();
        srcy++, trgy++)
    {
      // get the current pixel
      currPixel = this.getPixel(srcx,srcy);

      /* copy the color of currPixel into target
       */
      target.getPixel(trgx,trgy).setColor(currPixel.getColor());
    }
  };
  return target;
}
```

```
> Picture p = new Picture(FileChooser.pickAFile());
> p
Picture, filename D:\cs1316\MediaSources\guy1-left.jpg height 200
width 84
> Picture flipp = p.flip();
> flipp.show();
```

* * *

Figure 2.4: Flipping our guy character–original (left) and flipped (right)

Common Bug: Width is the size, not the coordinate
Why did we subtract one from getWidth() (which defaults to **this**.getWidth() to set the target X coordinate (trgx)? getWidth() returns the *number of pixels* across the picture. But the last *coordinate* in the row is one less than that, because Java starts all arrays at *zero*. Normal everyday counting starts with one, and that's what getWidth() reports.

2.5 Exploring Sound in Java

We can create sounds in an analogous way to how we're creating pictures.

```
> Sound s = new Sound(FileChooser.pickAFile());
> s.play();
```

How it works: Just as with pictures, we can create sounds as we declare them. FileChooser is an object that knows how to pickAFile(). That method puts up a file picker, then returns a string (or **null**, if the user hits CANCEL). Instances of the class Sound know how to play().

But what if we get it wrong?

```
> s.play()
> s.show()
Error: No 'show' method in 'Sound'
> Picture.play()
Error: No 'play' method in 'Picture'
> anotherpicture.play()
Error: Undefined class 'anotherpicture'
```

You can't ask a Sound object to show()—it doesn't know how to do that. Picture doesn't know how to play() nor how to show()—it's the *instances* (objects of that type or class) that know how to show(). The point of this example isn't to show you Java's barking messages, but to show you that there is no bite there. Type the wrong object name? Oh well—try again.

2.6 Exploring Music in Java

We will be working a lot with *MIDI* in this class. MIDI is a standard representation of musical information. It doesn't record sound. It records notes—when they're pressed, when they're released, how hard they're pressed, and what instrument is being pressed upon.

To use MIDI, we have to **import** some additional libraries. We're going to be using *JMusic* which is a wonderful Java music library that is excellent for manipulating MIDI.

```
> import jm.util.*;
> import jm.music.data.*;
> Note n1;
> n1 = new Note(60,0.5);
> // Create an eighth note at C octave 4
```

How it works: First, you'll see a couple of **import** statements to bring in the basics of JMusic. Note is the name of the class that represents a musical note object. We're declaring a note variable named n1. We then create a Note instance. We don't need a filename—we're not reading a JPEG or WAV file. Instead, we simply need to know *which* note and for what duration (0.5 is an eighth note). That last line looks surprisingly like English, because it is. Any line starting with "//" is considered a *comment* and is ignored by Java. Table 2.1 summarizes the relationships between note numbers and more traditional keys and octaves.

But this isn't actually enough to play our note yet. A note isn't music, at least not to JMusic.

```
> Note n2=new Note(64,1.0);
> View.notate(n1);

Table 2.1: MIDI notes

Figure 2.5: Just two notes

How it works: You'll see that we can't notate() a single note. We can, however, create a phrase that can take two notes (with different durations) Figure 2.5. A Phrase of JMusic knows how to addNote(). A View object knows how to notate() a phrase of music in standard Western music notation. From this window, we can actually play our music, change parameters (like the speed at which it plays), and shift instruments (e.g., to accordion or wind chimes or steel drums). We'll do more with the window later.

JMusic is a terrific example of using objects to *model*. JMusic is really modelling music.

- Note objects have tones and durations.
- Musical Phrase objects are collections of notes.
- A View object can present a musical phrase to us.

We can break this down in terms of what objects *know* and what they *do*.

	What instances of this class *know*	**What instances of this class *do***
Note	A musical pitch and its duration.	(Nothing we've seen yet.)
Phrase	Notes in the phrase.	addNote(aNote)

Ex. 1 — Create a constructor for Student that takes a name and an ID.

3 Methods in Java: Manipulating Pictures

Chapter Learning Objectives

To make wildebeests charge over the ridge or villagers move around in the town square, we need to be able to manipulate pictures. We manipulate pictures using *methods*, the bits of behavior that classes store for use on their instances. That's the focus of this chapter.

The computer science goals for this chapter are:

- To be able to use Java with control over details, like expressions, understanding what **public** means, and being able to use correctly the ubiquitous **public static void** main(String[] args).
- To compile and execute your code.
- To create a variety of different kinds of methods, including those that return values.
- To use JavaDoc.
- To chain method calls for compact, powerful expressions.
- To start our discussion of data structures with arrays.

The media learning goals for this chapter are:

- To extend what we can do with pictures.
- To combine methods for powerful picture manipulation.

3.1 Reviewing Java Basics

Assignment

As we saw in the last chapter, assignments come in form of

CLASSNAME VARIABLE = EXPRESSION;
or simply (if the variable has already been declared)
VARIABLE = EXPRESSION;

As mentioned, we can't declare variables twice in the same scope, and you can't use a variable of one type (or class) with an expression that results in an incompatible type. You can't assign a string to an **int** variable, for example,

Making It Work Tip: DrJava will declare for you–maybe not a good thing

If snd is an undeclared variable, DrJava will actually allow you to execute snd = **new** Sound("D:/myfile.wav");. DrJava is smart enough to figure out that you must mean for snd to be of type Sound. My suggestion: Don't do it. Be explicit in your type declarations. It will be too easy and forget when you're in Java Code Pane.

There are rules about *Java programming style* that you should know about. These aren't rules that, if broken, will result in a compiler error (usually). These are rules about how you write your code so that other Java programmers will understand what you're doing. We might call them *discourse rules*—they're the standard style or ways of talking in Java that Java programmers use.

- Always capitalize your class names.
- Never capitalize instance names, instance variable (sometimes called *fields*) names, or method names.
- You can use mixedCaseToShowWordBreaks in a long name.

All Java statements end with a semi-colon. You can insert as many spaces or returns (press the ENTER key) as you want in an expression—it's the semi-colon that Java uses to indicate the end of the line. Indentation doesn't matter at all in Java, unlike in Python. You can have no indentation at all in Java! Of course, no one, including you, will be able to make out what's going on in your program if you use no indentation at all. You probably should indent as we do here, where the body of a loop is indented deeper than the loop statement itself. DrJava will take care of that for you to make it easier to read, as will some other Java Integrated Development Environments (*IDE*s).

What goes in an expression? We can use +, −, ∗ and / exactly as you used them in whatever your first programming language was. An expression that you've seen several times already is **new** CLASSNAME(), sometimes with inputs like **new** Picture("C:/mypicture.jpg"). You may have already noted that sometimes you create a new class with inputs, and sometimes you don't. Whether or not you need inputs depends on the *constructor*s for the given class—those are methods that take inputs (optionally) and do something to set up the new object. For example, when we created

a new Note with a pitch and a duration, we passed the specification of the pitch and duration in as input to the class Note and they were assembled into the new object.

Java has a handful of shortcuts that you will see frequently. Because the phrase x = x + 1 (where x could be any integer variable) occurs so often, we can abbreviate it x++. Because the phrase y=y−1 occurs so often, it can be abbreviated as y−−. There's a general form, too. The phrase x = x + y can be shortened to x += y. There are similar abbreviations x ∗= y, x /= y, and x −= y.

Arrays

An array is a homogenous (all the same type) linear collection of objects which are compacted together in memory. An array of integers, then, is a whole bunch of numbers (each without a decimal place), one right after another in memory. Being all scrunched together in memory is about as efficient in terms of memory space as they can be, and they can be accessed very quickly–going from one to the other is like leaving your house and going to the one next door.

An array is declared with square brackets []. It turns out that the square brackets can come before or after the variable name in a declaration, so both of the below are correct Java statements (though clearly not both in the same scope!).

```
Pixel[] myPixels;
Pixel myPixels[];
```

To access an array, we'll use square brackets again, e.g., myPixels[0], which gets the first element in the array. Java begins numbering its indices at zero.

Conditionals

You've seen already that conditionals look like this:

```
if (LOGICAL-EXPRESSION)
   then-statement;
```

As you would expect, the logical expression can be made up of the same logical operators you've used before: <,>,<=,>=,==. Note that == is the test for equivalence–it is not the assignment operator =. Depending on other languages you've learned, you may have used the words and and or for chaining together logical statements, but not in Java. In Java, a logical *and* is &&. A logical *or* is ||.

The then−statement part can be one of two things. It could just be a simple statement ending in a semi-colon (e.g., pixel.setRed(0);. Or it could be any number of statements (each separated by semi-colons) inside of curly braces, like this:

```
if (pixel.getRed()<25)
{
   pixel.setRed(0);
   pixel.setBlue(120);
}
```

Do you need a semi-colon after the last curly brace? No, you don't have to, but if you do, it's not wrong. All of the below are correct conditionals in Java.

```
if (thisColor == myColor)
    setColor(thisPixel,newColor);
if (thisColor == myColor)
  {setColor(thisPixel,newColor);}
if (thisColor == myColor)
   {x = 12;
    setColor(thisPixel,newColor);};
```

We call those curly braces a *block*. A block is a single statement to Java. All the statements in the block together are considered just one statement. Thus, we can think of a Java statement ending in a semi-colon or a right curly brace (like an English sentence can end in "." or "!" or "?").

After the block for the *then* part (the part that gets executed "if" the logical expression is true, as in "if this, then that") of the **if**, you can have the keyword **else**. The **else** keyword can be followed with another statement (or another block of statements) that will be executed if the logical expression is *false*. You can't use the **else** statement if you end the *then* block with a semi-colon though (like in the last **if** in the example above). Java gets confused if you do that, and thinks that you're trying to have an **else** without an **if**.

Iteration: While and For

A **while** loop looks like an **if**:

```
while (LOGICAL-EXPRESSION)
   statement;
```

But they're not at all similar. An **if** tests the expression *once* then possibly executes the *then* statement. A **while** tests, and if true, executes the statement—then tests again, and again executes the statement, and repeats until the statement is no longer true. That is, a **while** statement *iterates*.

We can use a **while** for addressing all the pixels in an image and setting all the red values to zero.

```
> p
Picture, filename D:/cs1316/MediaSources/Swan.jpg height 360 width
480
```

```
> Pixel [] mypixels = p.getPixels();
> int index = 0;
> while (index < mypixels.length)
    {mypixels[index].setRed(0);
     index++;};
```

How it works: Notice the reference to mypixels.length above. This is the standard way of getting an array's length. The expression .length isn't referring to a method. Instead it's referring to an *instance variable* or *field*. Every array knows an instance variable that provides its length, but each length is an instance variable unique to that instance. It's all the same name, but it's the right value for each array.

Recall that **for** loop is unusual. It lists *initialization* (something to be done before the loop starts), *continuing condition* (something to test at the top of each loop), and *an incrementing condition* (what to do after testing at the top of each loop). It's actually the same structure as in the programming languages C and C++. We can use a **for** loop to count from one value to another, just as you might use a **for** loop in Basic or Python. But you can also use the Java **for** loop to do a lot more, like walk through both the x and y values at once.

Here's the same example as the **while** loop above, but with a **for** loop:

```
> for (int i=0; i < mypixels.length ; i++)
  { mypixels[i].setRed(0);};
```

How it works: Our *initialization* part is declaring an integer (**int**) variable i and setting it equal to zero. Notice that i will *ONLY* exist within the **for** loop. On the line afterward, i won't exist–Java will complain about an undeclared variable. The *continuing condition* is i $<$ mypixels.length. We keep going until i is equal to the length, and we *don't* execute when i is equal to the length. The *incrementing condition* is i++–increment i by one. What this does is to make i take on every value from 0 to mypixels.length-1 (minus one because we stop when i *IS* the length), and execute the body of the loop—which sets red of the pixel at i equal to zero.

3.2 Java is about Classes and Methods

In Java, nearly everything is an object. Objects *know* things and *know how to do* things. It's the objects that do and know things–there aren't globally accessible functions like there are in many other languages like Python, C, or Java.

Programming in Java (and object-oriented languages, in general) is about defining what these objects know and what they know how to do. Each object belongs to a *class*. The class defines what the object knows (its *instance variables* or *fields*) and what it knows how to do (its *methods*).

For the Picture object, there is a file named `Picture.java` that defines the fields and methods that all Picture objects know (Figure 3.1). That file

starts out with the line **public class** Picture. That starts out the definition of the class Picture. Everything inside the curly braces after that line is the definition of the class Picture.

Typically, we define at the top of the file the instance variables that *all* objects of that class know. We define the methods that all the instance variables of that class below that, but still within the curly braces of the class definition. Each object (e.g., each Picture instance) has the same instance variables, but different values for those variables–e.g., each picture has a filename where it read its file from, but they can all be different files. But all objects know the same methods–they *know how to do* the same things.

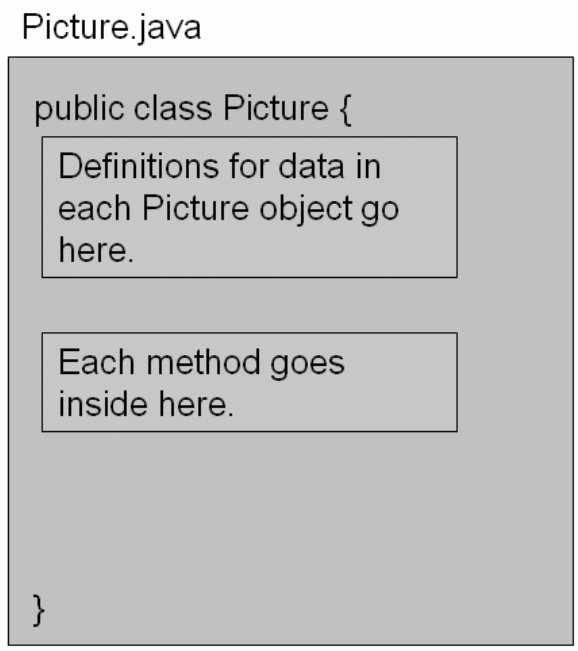

Figure 3.1: Structure of the Picture class defined in Picture.java

Debugging Tip: You change Picture.java

There should be one and only one `Picture.java` file. This means that you *have to* modify the file that we give you. If you rename it (say, `Picture-v2.java`), Java will just complain about the filename being incorrect. If you save `Picture.java` somewhere else, Java will get confused about two versions. Save a backup copy somewhere, and trust that it will be okay–you won't damage the file too severely.

* * *

So what's this **public** statement about the class Picture? You might be wondering if there are other options, like discreet or celebrity. The statement **public** means that the class Picture is available for access by any other class. In general, *every* field or method can be **public**, or **protected** or **private**.

- **public** means that the class, field, or method is accessible by anyone. If there was a class with **public** fields, any other object could read those fields or change the values in them. Is that a good thing? Think about it–if objects represent (model) the real world, can you read any value in the world or change it? Not usually.

- **private** means that the field or method can *only* be accessed by the class containing that field or method. That's probably the best option for fields. Some methods might be **private**, but probably most would be **public**.

- **protected** is a middle ground that doesn't generally work. It means that the field or method is accessible by any class or its subclass– or any class belonging to the same *package*. "Package?" you say. "I haven't seen anything about packages!" Exactly–and if you don't deal with packages, **protected** data and methods are essentially **public**. Makes sense? Not to me either.

Pictures are about arrays and pixels

A picture is a two-dimensional array of pixels. An array is typically one-dimensional—there's just a collection of values, one right after the other. In a one-dimensional array, each element has a number associated with it called a *index variable*—think of it as the mailbox address for each element. A two-dimensional array is called a *matrix*—it has both height and width. We usually number the columns and the rows. With pictures, upper left hand corner is row number 0 (which we will refer to as the y index) and column number 0 (which we will refer to as the x index). The y values increase going down, and the x values increase going to the right.

What is in those columns and rows is *pixels*. A pixel is a picture element—a small dot of color in the picture or on the screen. Each dot is actually made up of a red component, a green component, and a blue component. Each of those components can have a value between 0 and 255. A red value of 0 is no red at all, and a red value of 255 is the maximum red. All the colors that we can make in a picture are made up of combinations of those red, green, and blue values, and each of those pixels sits at a specific (x, y) location in the picture.

A method for decreasing red

Let's explore a method in the class Picture to see how this all works. Here's the method to decrease the red in a picture, which would be inserted in `Picture.java` within the curly braces defining the class.

Program Example #12

Example Java Code: **decreaseRed in a Picture**

```
/**
 * Method to decrease the red by half in the current picture
 */
public void decreaseRed()
{
  Pixel pixel = null; // the current pixel
  int redValue = 0;       // the amount of red

  // get the array of pixels for this picture object
  Pixel[] pixels = this.getPixels();

  // start the index at 0
  int index = 0;

  // loop while the index is less than the length of the pixels array
  while (index < pixels.length)
  {
    // get the current pixel at this index
    pixel = pixels[index];
    // get the red value at the pixel
    redValue = pixel.getRed();
    // set the red value to half what it was
    redValue = (int) (redValue * 0.5);
   // set the red for this pixel to the new value
    pixel.setRed(redValue);
    // increment the index
    index++;
  }
}
```

We would use this method like this:

```
> Picture mypic = new Picture("C:/intro-prog-java/mediasources/Barbara.jpg");
> mypic.show(); // Show the picture
> mypic.decreaseRed();
> mypic.repaint(); // Update the picture to show the changes
```

The first line creates a picture (**new** Picture...), declares a variable mypic to be a Picture, and assigns mypic to the new picture. We then show the

picture to get it to appear on the screen. The third line *calls* (or *invokes*) the method decreaseRed on the picture in mypic. The fourth line, mypic.repaint();, tells the picture to update itself on the screen. decreaseRed changes the pixels within memory, but repaint tells the window on the screen to update from memory.

How it works: Note that this method is declared as returning **void**—that means that this method doesn't return anything. It simply changes the object that it has been invoked upon. It's **public** so anyone (any object) can invoke it.

At the beginning of the method, we typically declare the variables that we will be using. We will be using a variable pixel to hold each and every pixel in the picture. It's okay to have a variable pixel whose class is Pixel—Java is case sensitive so it can figure out the variable names from the case names. We will use a variable named redValue to store the red value for each pixel before we change it (decrease it by 50%). It will be an integer (no decimal part) number, so we declare it **int**.

Making It Work Tip: Give variables values as you declare them

It's considered good practice to give initial values to the variables as you declare them. That way you know what is in there when you start, because you put it in there.

We give redValue an initial value of zero. We give pixel an initial value of **null**. **null** is the value that says, "This variable holds an object, but right now, it's holding nothing at all." **null** is the nothing-object.

The next line in decreaseRed is the statement that both declares the array of pixels pixels and assigns the name to an array. The array that we assign it to is what the method getPixels() returns. (That's the method getPixels which takes no inputs, but we still have to type () to tell Java that we want to call the method.) getPixels is a really useful method that returns all those pixels that are in the picture, but in linear, single-dimension array. It converts them from the matrix form to an array form, to make them easier to process. Of course, as an array, we lose the ability to know what row or column a pixel is in, but if we're doing the same thing to all pixels, we really don't care.

Notice that the object that we invoke getPixels() on is **this**. What's **this**? The object that we invoked decreaseRed on. In our example, we are calling decreaseRed on the picture in mypic (`barbara.jpg`). So **this** is the picture in `barbara.jpg`.

We are going to use a variable named index to keep track of which pixel we are currently working on in this method. The first index in any array is 0, so we start out index as 0. We next use a **while** loop to process each pixel in the picture. We want to keep going as long as index is less than the

number of pixels in the array. The number of elements in the array pixels is pixels.length.

length is not a method—it's a *field* or an *instance variable*. It's a value, not a behavior. We access it to get the number of elements in an array. Every array has the field length.

Common Bug: The maximum index is $length - 1$

A common mistake when working with arrays is to make the index go until $length$. The length is the *number* of elements in the array. The index numbers (the addresses on the array elements) start at 0, so the maximum index value is $length-1$. If you try to access the element at index $length$ you will get an error that says that you have an OutOfBoundsException—you've gone beyond the bounds of the array.

The body of the **while** loop in decreaseRed will execute repeatedly as long as index is less than $pixels.length$. Within the loop, we:

- Get the pixel at address index in the array pixels and make variable pixel refer to that pixel.
- Get the redness out of the pixel in variable pixel by calling the method getRed() and store it in redValue.
- We make redValue 50% smaller by setting it to 0.5 times itself. Notice that multiplying redValue by 0.5 could result in a value with a decimal point (think about odd values). But redValue can only be an integer, a value with no decimal point. So, we have to force the return value into an integer. We do that we *cast* the value into an integer, i.e., **int**. By saying "(**int**)" before the value we are casting ("(redValue $*$ 0.5)"), we turn it into an integer. There's no rounding involved—any decimal part simply gets hacked off.
- We then store the new redValue back into the pixel with setRed(redValue). That is, we invoke the method setRed on the pixel in the variable pixel with the input redValue: pixel.setRed(redValue);.
- Finally, we increment index with index++;. That makes index point toward the next value in the array, all set for the test at the top of the **while** and the next iteration through the body of the array.

Method with an input

What if we wanted to decrease red by an *amount*, not always 50%? We could do that by calling decreaseRed with an input value. Now, the code we just walked through cannot take an input. Here's one that can.

* * *

Example Java Code: **decreaseRed with an input**

Program Example #13

```
/**
 * Method to decrease the red by an amount
 * @param amount the amount to change the red by
 */
public void decreaseRed(double amount)
{
  Pixel[] pixels = this.getPixels();
  Pixel p = null;
  int value = 0;

  // loop through all the pixels
  for (int i = 0; i < pixels.length; i++)
  {
    // get the current pixel
    p = pixels[i];
    // get the value
    value = p.getRed();
    // set the red value the passed amount time what it was
    p.setRed((int) (value * amount));
  }
}
```

How it works: This version of decreaseRed has something within the parentheses after the method name—it's the amount to multiply each pixel value by. We have to tell Java the type of the input value. It's **double**, meaning that it's a double-precision value, i.e, it can have a decimal point.

In this method, we use a **for** loop. A **for** loop has three parts to it:

- An initialization part, a part that occurs before the loop begins. Here, that's **int** i = 0. There are semi-colons before each part.
- A test part—what has to be true for the loop to continue. Here, it's that we have more pixels left, i.e., i < pixels.length.
- An iteration part, something to do each time through the loop. Here, it's i++, go to the next index value (in variable i).

The rest of this loop is much the same as the other. *It's perfectly okay with Java to have both versions of decreaseRed in the Picture class at once.* Java can tell the difference between the version that takes no inputs and the one that takes one numeric input. We call the name, the number of inputs, and the types of the inputs as the *method signature*. As long as

two methods had different method signatures, it's okay for them to both have the same name.

Notice the odd comment at the start of the method, the one with the @param notation in it. That specialized form of comments is what's used to produce the documentation called *JavaDoc*. The JavaDoc for the media classes provided with this book is in the `doc` folder inside the `media-sources` folder. These Web pages explain all the methods, their inputs, how they're used, and so on (Figure 3.2). We sometimes refer to this information as the *API* or *Application Program Interface*. The content comes from these specialized comments in the Java files.

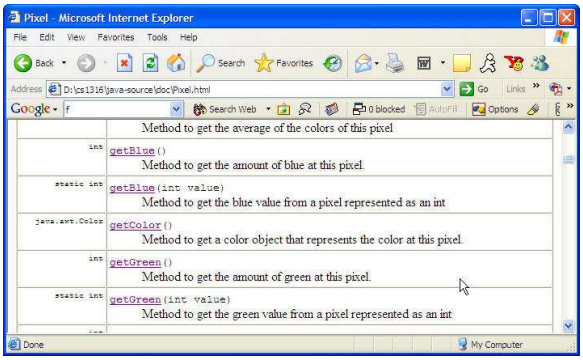

Figure 3.2: Part of the JavaDoc page for the Pixel class

Now, if you look at the class Picture, you may be surprised to see that it doesn't know very much at all. Certainly, important methods like show and repaint are missing. Where are they? If you edit the class Picture (in the file `Picture.java`), you'll see that it says:

```
public class Picture extends SimplePicture
```

That means that some of what the class Picture understands is actually defined in the class SimplePicture. Class Picture *extends* class SimplePicture. Picture is a subclass of SimplePicture, which means that class Picture *inherits* everything that SimplePicture has and knows. It's SimplePicture that actually knows about pixels and how pictures are stored, and it's SimplePicture that knows how to show and repaint pictures. Picture inherits all of that by being a *subclass* of SimplePicture.

Why do that? Why make Picture so relatively dumb? There are lots of reasons for using inheritance. The one we're using here is *information hiding*. Open up `SimplePicture.java` and take a peek at it. It's pretty technical and sophisticated code, filled with BufferedImage objects and references to Graphics contexts. We *want* you to edit the Picture class, to change methods and add new methods. We want that code to be understandable, so we hide the stuff that is hard to understand in SimplePicture.

3.3 Methods that return something: Compositing images

If we're going to make wildebeests or villagers, we need some way of getting those images onto a frame. Here are some methods to do it. Along the way, we will create methods that return new pictures—a very useful feature for creating more complex pictures.

Example Java Code: **Method to compose this picture into a target** *Program Example #14*

```
/**
 * Method to compose this picture onto target
 * at a given point.
 * @param target the picture onto which we chromakey this picture
 * @param targetx target X position to start at
 * @param targety target Y position to start at
 */
public void compose(Picture target, int targetx, int targety)
{
  Pixel currPixel = null;
  Pixel newPixel = null;

  // loop through the columns
  for (int srcx=0, trgx = targetx; srcx < this.getWidth();
       srcx++, trgx++)
  {

    // loop through the rows
    for (int srcy=0, trgy=targety; srcy < this.getHeight();
         srcy++, trgy++)
    {

      // get the current pixel
      currPixel = this.getPixel(srcx,srcy);

      /* copy the color of currPixel into target,
       * but only if it'll fit.
       */
      if (trgx < target.getWidth() && trgy < target.getHeight())
      {
        newPixel = target.getPixel(trgx,trgy);
        newPixel.setColor(currPixel.getColor());
      }
    }
  }
}
```

* * *

Using this method, we can then compose the guy into the jungle like this (Figure 3.3).

```
> Picture p = new Picture(FileChooser.getMediaPath("guy1-left.jpg"));
> Picture bg = new Picture(FileChooser.getMediaPath("jungle.jpg"));
> p.compose(bg,65,250);
> bg.show();
> bg.write("D:\\cs1316\\jungle-composed-with-guy.jpg")
```

Figure 3.3: Composing the guy into the jungle

How it works: Basically what happens in this method is that we copy the colors out of the source picture, **this**, and set the pixels in the target to that color. That makes this picture appear in the target.

The compose method takes three inputs. The first one is a picture onto which the **this** picture (the one that the method is being invoked upon) will be composed. Think of the input as a canvas onto which we paint this picture. The other two inputs are the x and y position where we start painting the picture—the variables targetx and targety are integers that define where the upper left hand corner of this picture appears.

We don't have the luxury of using getPixels this time. We need to know which rows and columns are which, so that we make sure that we copy them all into the right places. We don't want this picture (our source) to show up as one long line of pixels—we want the rows and columns in the source to show up as rows and columns in the target.

We are going to need two **for** loops. One is going to take care of the x indices, and the other will take care of the y indices. We use two variables for keeping track of the current pixel in **this** picture, our source. Those variables are named srcx and srcy. We use two other variables for keeping track of the current location in the target, trgx and trgy. The trick to a composition is to always increment srcx and trgx together (so that we're talking about columns in the course and the target at the same time), and srcy and trgy together (so that the rows are also in synch). You don't want

to start a new row in the source but not the target, else the picture won't look right when composed.

To keep them in synch, we use a **for** loop where we move a couple of expressions in each part. Let's look at the first one in detail.

```
for (int srcx=0, trgx = targetx; srcx < this.getWidth();
     srcx++, trgx++)
```

- In the initialization part, we declare srcx and set it equal to zero, then declare trgx and have it start out as the input targetx. Notice that declaring variables here is *the same as* (for the **for** loop) declaring them inside the curly braces of the **for** loop's block. This means that those variables *only* exist in this block—you can't access them after the class ends.

- In the testing part, we keep going as long as we have more columns of pixels to process in the source—that is, as long as srcx is less than the maximum width of this picture, **this**.getWidth().

- In the increment part, we increment srcx and trgx together.

Common Bug: Don't try to change the input variables

You might be wondering why we copied targetx into trgx in the compose method. While it's perfectly okay to use methods on input objects (as we do in compose() when we get pixels from the target), and maybe change the object that way, don't try to add or subtract the values passed in. It's complicated why it doesn't work, or how it does work in some ways. It's best just to use them as variables you can *read* and *call methods on*, but not *change*.

The body of the loop essentially gets the pixel from the source, gets the pixel from the target, and sets the color of the target pixel to the color of the source pixel. There is one other interesting statement to look at:

```
if (trgx < target.getWidth() && trgy < target.getHeight())
```

What happens if you have a really wide source picture and you try to compose it at the far right edge of the target? You can't fit all the pixels, of course. But if you write code that *tries* to access pixels beyond the edge of the target picture, you will get an error about OutOfBoundsException. This statement prevents that.

The conditional says that we *only* get the target pixel and set its color, if the x and y values that we're going to access are less than the maximum

width of the target and the the maximum height of the target. We stay well inside the boundary of the picture that way[1].

So far, we've only only seen methods that return **void**. We get some amazing expressive power by combining methods that return other objects. Below is an example of how we use the methods in class Picture to scale a picture larger (or smaller).

```
> // Make a picture from a file selected by the user
> Picture doll = new Picture(FileChooser.pickAFile());
> Picture bigdoll = doll.scale(2.0);
> bigdoll.show();
> bigdoll.write("bigdoll.jpg"); //Store the new picture to a new
file
```

Program Example #15

Example Java Code: **Method for Picture to scale by a factor**

```
/**
 * Method to scale the picture by a factor, and return the result
 * @param scale factor to scale by (1.0 stays the same,
 *    0.5 decreases each side by 0.5, 2.0 doubles each side)
 * @return the scaled picture
 */
public Picture scale(double factor)
{
  Pixel sourcePixel, targetPixel;
  Picture canvas = new Picture(
          (int) (factor*this.getWidth())+1,
          (int) (factor*this.getHeight())+1);
  // loop through the columns
  for (double sourceX = 0, targetX=0;
       sourceX < this.getWidth();
       sourceX+=(1/factor), targetX++)
  {
    // loop through the rows
    for (double sourceY=0, targetY=0;
         sourceY < this.getHeight();
         sourceY+=(1/factor), targetY++)
    {
      sourcePixel = this.getPixel((int) sourceX,(int) sourceY);
      targetPixel = canvas.getPixel((int) targetX, (int) targetY);
      targetPixel.setColor(sourcePixel.getColor());
    }
  }
  return canvas;
```

[1]Of course, if you try to compose to the *left* of the picture, or *above* it, by using negative starting index values, you will get an exception still.

```
}
```

How it works: The method scale takes as input the amount to scale the picture **this**. This method is declared type Picture, instead of **void**—scale returns a picture.

The basic process of scaling isn't too complicated. If we have a picture and want it to fit into a smaller space, we have to lose some pixels—we simply can't fit all the pixels in. (All pixels are basically the same size, for our purposes.) One way of doing that is to skip, say, every other pixel, by skipping every other row and column. We do that by adding two to each index instead of incrementing by one each time through the loop. That reduces the size of the picture by 50% in each dimension.

What if we want to scale *up* a picture to fill a large space? Well, we have to duplicate some pixels. Think about what happens if we add 0.5 to the index variable (either for x or y) each time through the loop. The values that the index variable will take will be $0, 0.5, 1.0, 1.5, 2.0, 2.5,$ and so on. But the index variable can only be an integer, so we'd chop off the decimal. The result is $0, 0, 1, 1, 2, 2,$ and so on. By adding 0.5 to the index variable, we end up taking each position twice, thus doubling the size of the picture.

Now, what if we want a different sizing–increase by 30% or decrease by 25%? That's where the factor comes in as the input to scale. If you want a factor of 0.25, you want the new picture to be $1/4$ of the original picture in each dimension. So what do you add to the index variable? It turns out that $1/factor$ works quite nice. $1/0.25$ is 4, which is a good index increment to get 0.25 of the size.

The scale method starts out by *creating* a target picture. The picture is sized to be the scaling factor times the height and width—so the target will be bigger if the scaling factor is over 1.0, and smaller if it is less. As we can see here, new instances of the class Picture can be created by filename *or* by specifying the height and width of the picture. The returned picture is blank. We add one to deal with off-by-one errors on oddly sized pictures.

The tricky part of this method is the **for** loops.

```
for (double sourceX = 0, targetX=0;
     sourceX < this.getWidth();
     sourceX+=(1/factor), targetX++)
```

Like in compose, we're manipulation two variables at once in this **for** loop. We're using **double** variables to store the indices, so that we can add a $1/factor$ to them and have them work, even if $1/factor$ isn't an integer. Again, we start out at zero, and keep going as long as there are columns (or rows, for the y variable) to process. The increment part has us adding one to targetX but doing sourceX += (1/factor) for the sourceX variable. This is a shortcut that is equivalent to sourceX = sourceX + (1/factor).

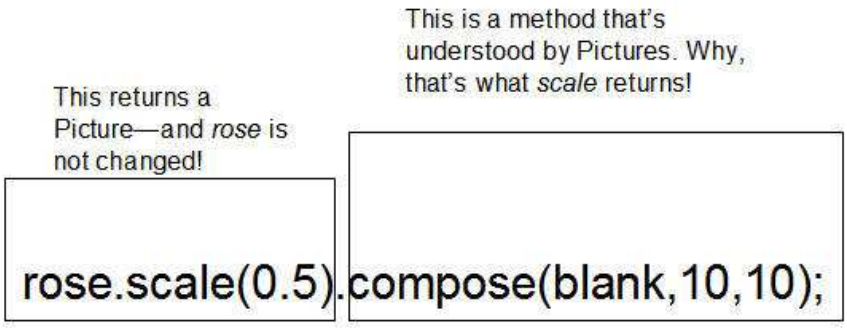
When we use the index variables, we cast them to integers, which removes the floating point part.

```
sourcePixel = this.getPixel((int) sourceX,(int) sourceY);
```

At the very of end of this method, we **return** the newly created picture. The power of returning a new picture is that we can now do a lot of manipulation of pictures with opening up only a few pictures and *never changing those original pictures*. Consider the below which creates a mini-collage by creating a new blank picture (by asking for a **new** Picture with a height and width as inputs to the constructor, instead of a filename) then composing pictures onto it, scaled at various amounts (Figure 3.4).

```
> Picture blank = new Picture(600,600);
> Picture swan = new Picture("C:/cs1316/MediaSources/swan.jpg");
> Picture rose = new Picture("C:/cs1316/MediaSources/rose.jpg");
> rose.scale(0.5).compose(blank,10,10);
> rose.scale(0.75).compose(blank,300,300);
> swan.scale(1.25).compose(blank,0,400);
> blank.show();
```

What's going on here? How can we *cascade* methods like this? It's because *all* pictures understand the same methods, whether they were created from a file or created from nothing. So, the *scaled* rose understands compose just as well as the rose itself does.



Sometimes you don't want to show the result. You may prefer to explore it, which allows you to check colors and get exact x and y coordinates for parts of the picture. We can explore pictures to figure out their sizes and where we want to compose them (Figure 3.5).

We also see in this example that we can use setMediaPath and getMediaPath to make it easier to get the pieces by basename instead of typing out the whole file path each time. FileChooser.setMediaPath remembers the path that you specify as the location of your media[2]. FileChooser.getMediaPath then recalls that path and sticks it *before* the base file name that you provide as input.

[2]The path is actually stored as a file on your disk, so you should only have to do setMediaPath once on a single computer

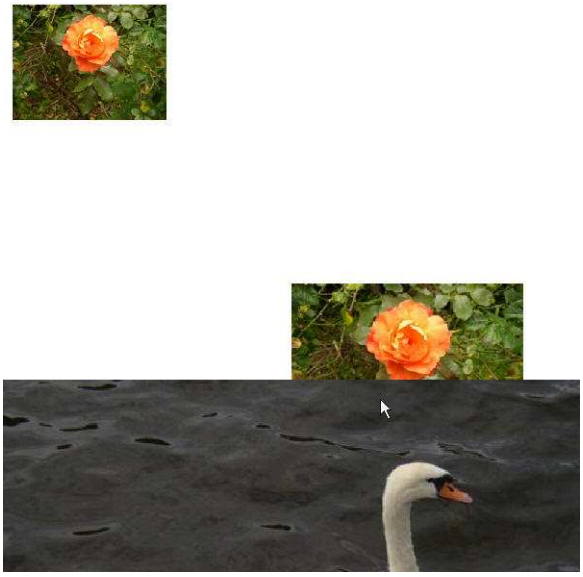


Figure 3.4: Mini-collage created with scale and compose

```
> FileChooser.setMediaPath("C:/cs1316/mediasources/");
> Picture bg = new Picture(FileChooser.getMediaPath("jungle.jpg"));
> bg.explore();
> p.explore();
```

Composing by Chromakey

Chromakey is the video technique by which a meteorologist on our television screen gestures to show a storm coming in from the East, and we see the meteorologist in front of a map (perhaps moving) where the storm is clearly visible in the East next to the meteorologist's hand. The reality is that the meteorologist is standing in front of a blue or green screen. The chromakey algorithm replaces all the blue or green pixels in the picture with pixels of a different background, effectively changing where it looks like the meteorologist is standing. Since the background pixels won't be all the *exact* same blue or green (due to lighting and other factors), we usually use a *threshold* value. If the blue or green is "close enough" (that is, within a threshold distance from our comparison blue or green color), we swap the background color.

There are a couple of different chromakey methods in Picture. chromakey() lets you input the color for the background and a threshold for how close you want the color to be. bluescreen() assumes that the background is blue, and looks for more blue than red or green (Figure 3.6. If there's a lot of blue

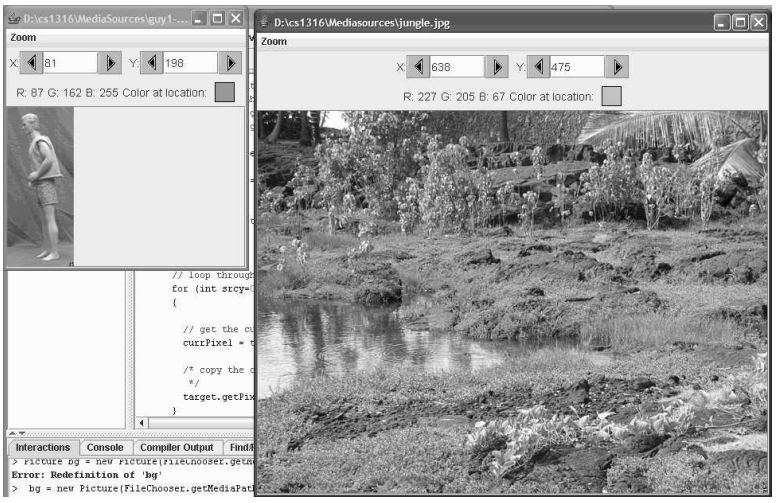

Figure 3.5: Using the explore method to see the sizes of the guy and the jungle

in the character, it's hard to get a threshold to work right. It's the same reason that the meteorologist doesn't wear blue or green clothes—we'd see right through them!

```
> Picture p = new Picture(FileChooser.getMediaPath("monster-right1.jpg"));
> Picture bg = new Picture(FileChooser.getMediaPath("jungle.jpg"));
> p.bluescreen(bg,65,250);
> import java.awt.*; //to get to colors
> p.chromakey(bg,Color.blue,100,165,200);
> p.chromakey(bg,Color.blue,200,26,250);
> bg.show();
> bg.write("D:/cs1316/jungle-with-monster.jpg");
```

Program Example #16

Example Java Code: **Methods for general chromakey and bluescreen**

```
/**
 * Method to do chromakey using an input color for background
 * at a given point.
 * @param target the picture onto which we chromakey this picture
 * @param bgcolor the color to make transparent
 * @param threshold within this distance from bgcolor, make transparent
 * @param targetx target X position to start at
 * @param targety target Y position to start at
```

Figure 3.6: Chromakeying the monster into the jungle using different levels of bluescreening

```
   */
10 public void chromakey(Picture target, Color bgcolor, int threshold,
                         int targetx, int targety)
12 {
     Pixel currPixel = null;
14   Pixel newPixel = null;

16   // loop through the columns
     for (int srcx=0, trgx=targetx;
18       srcx<getWidth() && trgx<target.getWidth();
         srcx++, trgx++)
20   {

22     // loop through the rows
       for (int srcy=0, trgy=targety;
24       srcy<getHeight() && trgy<target.getHeight();
         srcy++, trgy++)
26     {

28       // get the current pixel
         currPixel = this.getPixel(srcx,srcy);
30
         /* if the color at the current pixel is within threshold of
32        * the input color, then don't copy the pixel
          */
34       if (currPixel.colorDistance(bgcolor)>threshold)
         {
36         target.getPixel(trgx,trgy).setColor(currPixel.getColor());
         }
```

```
38        }
      }
40    }

42    /**
       * Method to do chromakey assuming blue background for background
44     * at a given point.
       * @param target the picture onto which we chromakey this picture
46     * @param targetx target X position to start at
       * @param targety target Y position to start at
48     */
      public void bluescreen(Picture target,
50                           int targetx, int targety)
      {
52      Pixel currPixel = null;
        Pixel newPixel = null;
54
        // loop through the columns
56      for (int srcx=0, trgx=targetx;
             srcx<getWidth() && trgx<target.getWidth();
58           srcx++, trgx++)
        {
60
          // loop through the rows
62        for (int srcy=0, trgy=targety;
               srcy<getHeight() && trgy<target.getHeight();
64             srcy++, trgy++)
          {
66
            // get the current pixel
68          currPixel = this.getPixel(srcx,srcy);

70          /* if the color at the current pixel mostly blue (blue value is
             * greater than red and green combined), then don't copy pixel
72           */
            if (currPixel.getRed() + currPixel.getGreen() > currPixel.getBlue())
74          {
              target.getPixel(trgx,trgy).setColor(currPixel.getColor());
76          }
          }
78      }
      }
```

3.4 Creating classes that do something

So far, we have created methods in the class Picture that know *how* to do something, but we actually *do* things with statements in the Interactions

Pane. How do we get a Java class to *do* something? We use a particular method that declares itself to be the main thing that this class *does*. You declare a method like this:

```
public static void main(String[] args){
 //code goes here
}
```

The code that goes inside a main method is exactly like what goes in an Interactions Pane. For example, here's a class that the *only* thing it does is to create a mini-collage.

Example Java Code: **A public static void main in a class** *Program Example #17*

```
public class MyPicture {

  public static void main(String args[]){

    Picture canvas = new Picture(600,600);
    Picture swan = new Picture("C:/cs1316/MediaSources/swan.jpg");
    Picture rose = new Picture("C:/cs1316/MediaSources/rose.jpg");
    Picture turtle = new Picture("C:/cs1316/MediaSources/turtle.jpg");

    swan.scale(0.5).compose(canvas,10,10);
    swan.scale(0.5).compose(canvas,350,350);
    swan.flip().scale(0.5).compose(canvas,10,350);
    swan.flip().scale(0.5).compose(canvas,350,10);
    rose.scale(0.25).compose(canvas,200,200);
    turtle.scale(2.0).compose(canvas,10,200);
    canvas.show();
  }
}
```

The seemingly-magical incantation **public static void** main(String [] args) will be explained more later, but we can talk about it briefly now.

- **public** means that it's a method that any other class can access.
- **static** means that this is a method accessible from the *class*. We don't need to create instances of this class in order to run the main method.
- **void** means that the main method doesn't return anything.
- String[] args means that the main method can actually take inputs *from the command line*. You can run a main method from the command line by typing the command java and the class name, e.g. java MyPicture (presuming that you have Java installed!).

To run a main method from within DrJava, use function key F2. That's the same as using RUN DOCUMENT'S MAIN METHOD from the TOOLS menu (Figure 3.7).

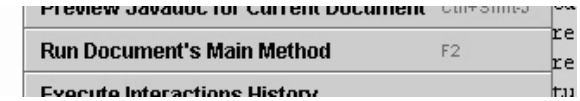

Figure 3.7: Run the main method from DrJava

A main method is not very object-oriented – it's not about defining what an object knows or what it can do. But it is pretty useful.

4 Objects as Agents: Manipulating Turtles

Chapter Learning Objectives

We are going to model our wildebeests and villagers as *agents*—objects that behave independent of each other, seemingly simultaneously, with a graphical (visible) representation. Turtles are an old computational idea that are useful for understanding agents behavior. They are also a powerful tool for understanding object-oriented programming. In this chapter, we learn about turtles in order to simply animations and simulations later.
The computer science goals for this chapter are:

- To introduce some of the history of object-oriented programming, from Logo (and turtles) to Smalltalk.
- To generalize an understanding of objects, from Pictures to Turtles.
- To understand better cascading methods.
- To introduce some basic list manipulation ideas, e.g., that nodes are different *objects*.

The media learning goals for this chapter are:

- To create animations using a FrameSequence.
- To find another technique for composing pictures.
- To use a simple technique for rotating pictures.

4.1 Turtles: An Early Computational Object

In the mid-1960's, Seymour Papert at MIT and Wally Feurzeig and Danny Bobrow at BBN Labs were exploring educational programming by children. That was a radical idea at the time. Computers were large, expensive devices which were shared by multiple people at once. Some found the thought of giving up precious computing time for use by 10 or 11 year old children to be ludicrous. But Papert, Feurzeig, and Bobrow believed

that the activity of programming was a great context for learning all kinds of things, including learning about higher-order thinking skills, like planning and debugging. They created the programming language *Logo* as a simplified tool for children.

The most common interaction with computers in those days was through teletypes—large machines with big clunky keys that printed all output to a roll of paper, like a big cash register receipt paper roll. That worked reasonably well for textual interactions, and much of the early use of Logo was for playing with language (e.g., writing a pig-Latin generator). But the Logo team realized that they really needed some graphical interaction to attract the kids with whom they were working. They created a robot *turtle* with an attached pen to give the students something to control to make drawings.

The simple robot turtle sat on a large piece of paper, and when it moved (and if its pen was "down" and touching the paper) it would draw a line behind it. The Logo team literally invented a new kind of mathematics to make Logo work (*XXX Cite Abelson and diSessa*), where the turtle didn't know Cartesian coordinates ((x, y) points) but instead knew it's heading (which direction it was facing), and could turn and go forward. This relative positioning (as opposed to global, Cartesian coordinates) was actually enough to do quite a bit of mathematics, including biological simulations and an exploration of Einstein's Special Theory of Relativity (*XXX Cite Abelson and diSessa*).

As we will see in the next section, the Logo turtle is very clearly a computational object, in our sense of object. The turtle *knows* some things (like its heading and whether its pen is down) and it can *do* some things (like turn and forward). But even more directly, the Logo turtle influenced the creation of object-oriented programming. Alan Kay (*XXX Cite "An Early History of Smalltalk"*) modeled his *Smalltalk* programming language on Logo—and Smalltalk is considered to be the very first object-oriented programming language (a direct influence on Java), and Alan Kay is considered to be the inventor of object-oriented programming.

The Logo turtle today still exists in many implementations of many languages, but has multiplied. Seymour Papert's student, Mitchel Resnick, developed a version of Logo, *StarLogo* with thousands of turtles that can interact with one another. Through this interaction, they can simulate scenarios like ants in an anthill, or termites, slime mold, or vehicle traffic[Resnick, 1997].

4.2 Drawing with Turtles

We're going to use turtles to draw on our pictures in interesting and flexible ways, and to simplify animation. (See the Appendix for what the Turtle class looks like.) Our Turtle class instances can be created on a Picture or on a World. Think of a World as a constantly updating picture that repaints automatically. We create a World by simply creating a **new** one. We create

a Turtle on this world by passing the World instance in as input to the Turtle constructor (Figure 4.1).

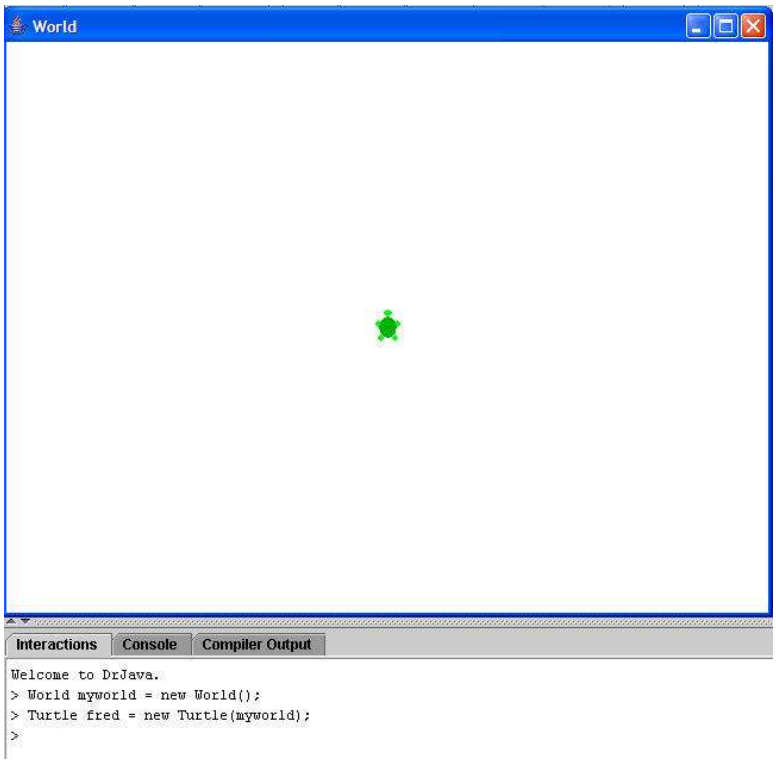

Figure 4.1: Starting a Turtle in a new World

Here's an example of opening a turtle on a Picture instead (Figure 4.2). Turtles can be created on blank Picture instances (which start out white) in the middle of the picture with pen down and with black ink. When a turtle is told to go forward, it moves forward the input number of *turtle steps* (think "pixels," which isn't *exactly* correct, but is close enough most of the time—the actual unit is computed by Java depending on your screen resolution) in whatever direction the turtle is currently facing. You can change the direction in which the turtle is facing by using the turn method which takes as input the number of degrees to turn. Positive degrees are clockwise, and negative ones are counter-clockwise.

```
> Picture blank = new Picture(200,200);
> Turtle fred = new Turtle(blank);
> fred
Unknown at 100, 100 heading 0
> fred.turn(-45);
```

```
> fred.forward(100);
> fred.turn(90);
> fred.forward(200);
> blank.show();
> blank.write("D:/cs1316/turtleexample.jpg")
```

Figure 4.2: A drawing with a turtle

Turtles know their position (unlike the original robot turtles) and their heading. The heading is 0 when straight up (how they're first created), and 90 when pointed to the right (due east), and 180 when pointed straight down. Clearly, turtles know things (e.g., their heading, x and y position) and can do things (e.g., like moving forward and turning).

```
> fred.forward(100);
> fred.turn(90);
> fred.getHeading()
90
> fred.getXPos()
320
> fred.getYPos()
140
```

Turtles can pick up their pen (stop drawing) using either the method penUp() or the code setPenDown(**false**). We can set the pen down using penDown() or setPenUp(**true**). Java does know about truth, or at least, about *Boolean* values: **true** and **false**.

To draw more complex shapes, we tell the turtle to do its basic steps repeatedly. Telling a turtle to go forward a certain number of steps and to turn 90 degrees makes a square.

```
> for (int sides=0; sides <= 3 ; sides++)
  {fred.forward(100); fred.turn(90);}
```

When cascades don't work

Here's a thought experiment: will this work?

```
> World earth = new World();
> Turtle turtle = new Turtle(earth);
> turtle.forward(100).right(90);
```

The answer is "no," but can you figure out why? Here's a hint: The error you get in the Interactions Pane is Error: No 'right' method in 'void' with arguments: (**int**). While the error message is actually telling you exactly what the problem is, it's written in *Javanese*—it presumes that you understand Java and can thus interpret the message.

The problem is that forward does not return anything, and certainly not a *turtle*. The method forward returns **void**. When we cascade methods like this, we are telling Java to invoke right(90) on what turtle.forward(100) returns. Since forward returns **void**, Java checks if instances of class **void** understand right. Of course not—**void** is nothing at all. So Java tells us that it checked for us, and the class **void** has no method right that takes an integer (**int**) input (e.g., 90 in our example). (Of course, **void** doesn't know anything about right with *any* inputs, but just in case we only got the inputs wrong, Java lets us know what it looked for.) Thus: Error: No 'right' method in 'void' with arguments: (**int**).

You can only use a cascade of method calls if the *previous* method call returns an object that has a method defined for the *next* method call. Since forward returns nothing (**void**), you can't cascade anything after it. Sure, we could create forward so that it does return the turtle **this**, the one it was invoked on, but one may ask if that makes any sense. Should forward return something?

Making lots of turtles

Using Mitchel Resnick's StarLogo as inspiration, we may want to create something with *lots* of turtles. For example, consider what this program draws on the screen.

Example Java Code: **Creating a hundred turtles** *Program Example #18*

```
public class LotsOfTurtles {
2
  public static void main(String[] args){
4   // Create a world
    World myWorld = new World();
6   // A flotilla of turtles
    Turtle [] myTurtles = new Turtle[100];
8
```

```
    // Make a hundred turtles
10  for (int i=0; i < 100; i++) {
      myTurtles[i] = new Turtle(myWorld);
12  }

14  //Tell them all what to do
    for (int i=0; i < 100; i++) {
16    // Turn a random amount between 0 and 360
      myTurtles[i].turn((int) (360 * Math.random()));
18    // Go 100 pixels
      myTurtles[i].forward(100);
20  }
  }
22 }
```

How it works: Study the program and think about it before you look at Figure 4.3.

- First we create a World and name it myWorld.
- Next, we create an array to store 100 Turtle instances. Notice that Turtle [] myTurtles = **new** Turtle[100]; *creates no turtles!*. That 100 is enclosed in square brackets—we're not calling the Turtle constructor yet. Instead, we're simply asking for 100 slots in an array myTurtles that will each be a Turtle.
- Inside a **for** loop that goes 100 times, we see myTurtles[i] = **new** Turtle(myWorld);. Here's where we're creating each of the 100 turtles in myWorld and putting each of them in their own slot of the array myTurtles.
- Finally, we tell each of the turtles to turn a random amount and go forward 100 steps. Math.random() returns a number between 0 and 1.0 where all numbers (e.g., 0.2341534) in that range are equally likely. Since that will be a **double**, we have to cast the result to **int** to use it as an input to forward.

Figured it out yet? It makes a circle of radius 100! This is an example from Mitchel Resnick's book that introduced StarLogo[Resnick, 1997].

Obviously, we can have more than one Turtle in a World at once. Instances of class Turtle know some methods that allow them to interact with one another. They know how to turnToFace(anotherTurtle) which changes the one heading to match the other. They also know how to compute getDistance(x,y) which is the distance from this turtle (the one that getDistance was invoked upon) to the point x, y. Thus, in this example, r2d2 goes off someplace random on tattoine, but c3po turns to face him and moves forward exactly the right distance to catch r2d2.

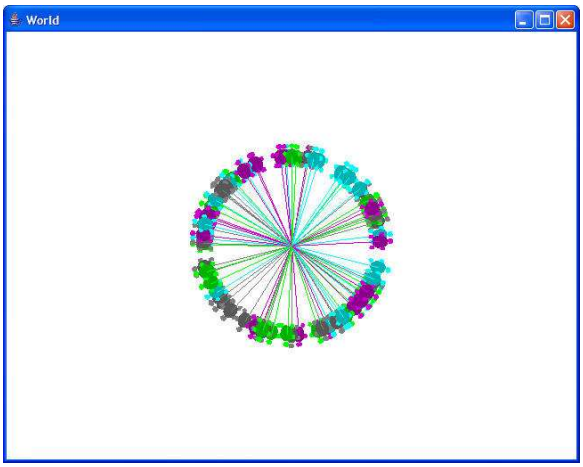

Figure 4.3: What you get with a hundred turtles starting from the same point, pointing in random directions, then moving forward the same amount

```
> World tattoine = new World();
> Turtle r2d2 = new Turtle(tattoine);
> r2d2.turn((int)
    (360 * Math.random()));
> r2d2.forward((int)
    (Math.random() * 100));
> Turtle c3po = new Turtle(tattoine);
> c3po.turnToFace(r2d2);
> c3po.forward((int)
    (c3po.getDistance(
        r2d2.getXPos(),r2d2.getYPos())));
```

Composing pictures with turtles

We saw earlier that we can place turtles on instance of class Picture, not just instances of class World. We can also use turtles to compose pictures into other pictures, through use of the drop method. Pictures get "dropped" *behind* (and to the right of) the turtle. If it's facing down (heading of 180.0), then the picture shows up upside down (Figure 4.4).

```
> Picture monster = new Picture(FileChooser.getMediaPath("monster-right1.jpg"));
> Picture newbg = new Picture(400,400);
> Turtle myturt = new Turtle(newbg);
> myturt.drop(monster);
> newbg.show();
```

We'll rotate the turtle and drop again (Figure 4.5).

Figure 4.4: Dropping the monster character

```
> myturt.turn(180);
> myturt.drop(monster);
> newbg.repaint();
```

Figure 4.5: Dropping the monster character after a rotation

We can drop using loops and patterns, too (Figure 4.6). Why don't we see 12 monsters here? Maybe some are blocking the others?

```
> Picture frame = new Picture(600,600);
> Turtle mabel = new Turtle(frame);
> for (int i = 0; i < 12; i++)
   {mabel.drop(monster); mabel.turn(30);}
```

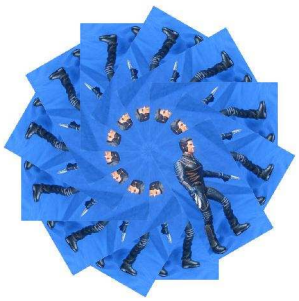

Figure 4.6: An iterated turtle drop of a monster

We can combine these in a main method to create a more complex image (Figure 4.7).

Example Java Code: **Making a picture with dropped pictures** *Program Example #19*

```
public class MyTurtlePicture {

  public static void main(String [] args) {
    Picture canvas = new Picture(600,600);
    Turtle jenny = new Turtle(canvas);
    Picture lilTurtle =
        new Picture(
          FileChooser.getMediaPath("Turtle.jpg"));

    for (int i=0; i <=40; i++)
    {
      if (i < 20)
      {jenny.turn(20);}
      else
      {jenny.turn(-20);}
      jenny.forward(40);
      jenny.drop(lilTurtle.scale(0.5));
    }
    canvas.show();
  }
}
```

* * *

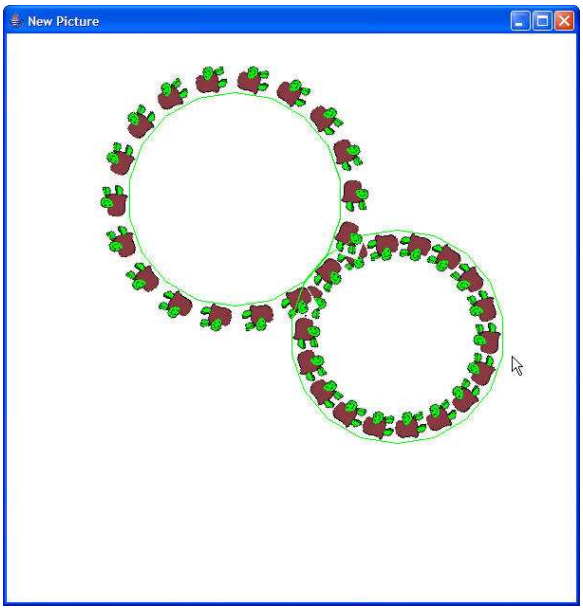

Figure 4.7: Making a more complex pattern of dropped pictures

4.3 Creating animations with turtles and frames

Our eyes tend to present an image to our brain, even for a few moments after the image as disappeared from sight. That's one of the reasons why we don't panic when we naturally blink (many times a minute without noticing)—the world doesn't go away and we don't see blackness. Rather, our eyes persist in showing the image in the brief interval when we blink—we call that *persistence of vision*.

A movie is a series of images, one shown right after the other. If we can show at least 16 images (*frames*) in a logical sequence in a second, our eye merges them through persistence of vision, and we perceive continuous motion. Fewer frames per second may be viewed as continuous, but it will probably be choppy. If we show frames that are not in a logical sequence, we perceive a montage, not continuous motion. Typical theater movies present at 22 frames per second, and video is typically 30 frames per second.

If we want to create an animation, then, we need to store a bunch of instances of Picture as frames, then play them back faster than 16 frames per second. We have a class for doing this, FrameSequence.

- The constructor for FrameSequence takes a path to a directory where frames will be stored as JPEG images, so that you might be able to reassemble them into a movie using some other tool (e.g., Windows

Movie Maker, Apple Quicktime Player, ImageMagick).

- A FrameSequence knows how to show(). Once shown, a FrameSequence will show each frame as it is added to the FrameSequence. When you first tell a FrameSequence to show, it will warn you that there's nothing to see until a frame is added.
- It knows how to addFrame(aPicture) to add another frame to a FrameSequence.
- It knows how to replay(delay) to show a sequence of frames back again. The delay is an integer for the number of milliseconds to wait between each frame. A delay of 62 is roughly 16 frames per second—anything around there or less will be perceived as continuous motion.

Here's a silly example of how you might use a FrameSequence. We're adding three (unrelated) pictures to a FrameSequence via addFrame. We can then replay the sequence back, one frame per second (or strictly, one frame per 1000 milliseconds).

```
> FrameSequence f = new FrameSequence("D:/Temp");
> f.show()
There are no frames to show yet.  When you add a frame it will be
shown
> Picture t = new
    Picture("C:/cs1316/MediaSources/Turtle.jpg");
> f.addFrame(t);
> Picture barb = new
    Picture("C:/cs1316/MediaSources/Barbara.jpg");
> f.addFrame(barb);
> Picture katie = new
    Picture("C:/cs1316/MediaSources/Katie.jpg");
> f.addFrame(katie);
> f.replay(1000); // Delay one frame per second
```

Let's combine turtles and a FrameSequence to make an animation of frames.

Example Java Code: **An animation generated by a Turtle**

Program Example #20

```
public class MyTurtleAnimation {

  private Picture canvas;
  private Turtle jenny;
  private FrameSequence f;

  public MyTurtleAnimation() {

```

```
    canvas = new Picture(600,600);
    jenny = new Turtle(canvas);
    f = new FrameSequence("C:/Temp/");
  }

  public void next(){
    Picture lilTurtle = new Picture(FileChooser.getMediaPath("Turtle.jpg"));

    jenny.turn(-20);
    jenny.forward(30);
    jenny.turn(30);
    jenny.forward(-5);
    jenny.drop(lilTurtle.scale(0.5));
    f.addFrame(canvas.copy());  // Try this as
                                // f.addFrame(canvas);
  }

  public void next(int numTimes){
    for (int i=0; i < numTimes; i++)
    {this.next();}
  }

  public void show(){
    f.show();
  }

  public void replay(int delay){
    f.show();
    f.replay(delay);
  }
}
```

We run this program like this:

```
> MyTurtleAnimation anim = new MyTurtleAnimation();
> anim.next(20); // Generate 20 frames
> anim.replay(500); // Play them back, two per second
```

How it works: An instance of MyTurtleAnimation has three instance variables associated with it: A Picture onto which the turtle will draw named canvas, a Turtle named jenny, and a FrameSequence. The constructor for MyTurtleAnimation creates the original objects for each of these three names.

Common Bug: Don't declare the instance variables

There's a real temptation to put "Picture" in front of that line in the constructor canvas = **new** Picture(600,600);. But resist it. Will it compile? Absolutely. Will it work? Not at all. If you declare canvas a Picture inside

of the constructor MyTurtleAnimation(), it *only* exists in the constructor. If you want it canvas to exist outside that method, you have to access the instance variable, the field created in the object. If you don't declare it in the constructor, Java figures out that you mean the instance variable.

There are two different next methods in MyTurtleAnimation. The one that we called in the example (where we told it to go for 20 steps) is this one:

```
public void next(int numTimes){
  for (int i=0; i < numTimes; i++)
  {this.next();}
}
```

All that next(**int** numTimes) does is to call next() the input numTimes number of times. So the real activity in MyTurtleAnimation occurs in next() with no inputs.

```
public void next(){
    Picture lilTurtle = new Picture(
        FileChooser.getMediaPath("Turtle.jpg"));

    jenny.turn(-20);
    jenny.forward(30);
    jenny.turn(30);
    jenny.forward(-5);
    jenny.drop(lilTurtle.scale(0.5));
    f.addFrame(canvas.copy());   // Try this as
                                 // f.addFrame(canvas);
}
```

The method next() does a bit of movement, a drop of a picture, and an addition of a frame to the FrameSequence. Basically, it generates the next frame in the animation sequence.

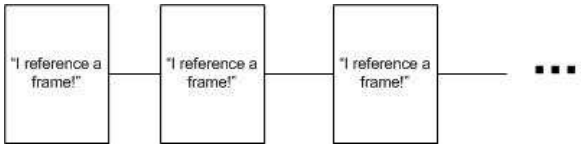
The show() and replay() methods *delegate* their definition to the FrameSquence instance. Delegation is where one class accomplishes what it needs to do by asking something else to do it. It's what you might call "passing the buck." An animation should know how to show() or codereplay(). The way that the animation accomplishes those tasks is by asking the **FrameAnimation** to show or replay.

Data structure within FrameSequence

Did you try this same animation with the last line of next changed to f.addFrame(canvas);? What happened? If you did try it, you may have thought you made a mistake. When you ran the next animation, you saw the animation play out as normal. But when you executed replay, you saw only the final frame appear —never any other frame. Go check the temporary directory where the FrameSequence wrote out its frames. You'll find a

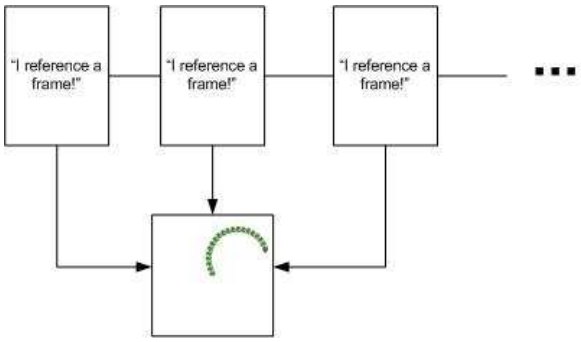
bunch of JPEG images there: `frame0001.jpg`, `frame0002.jpg`, and so on. So the animation did work and the FrameSequence did write out the frames. But why isn't it replaying correctly?

What we are seeing helps us to understand how FrameSequence works and what its internal data structure is. As you might imagine, a FrameSequence is a series of frames—but that's not correct in the details. The FrameSequence is actually a list of *references* to Picture objects. Each element in the FrameSequence refers to some Picture.

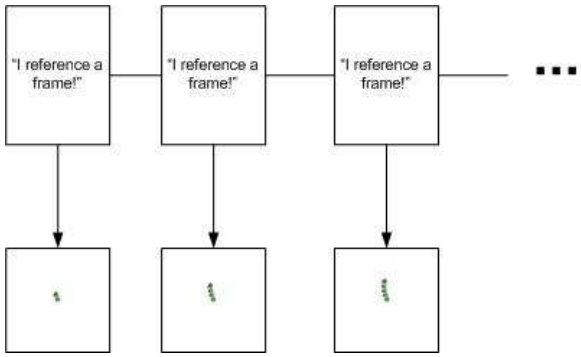


If a FrameSequence does not actually have any frames in it, where do the frames come from? From the Picture that you input to addFrame! That's what the FrameSequence frame references point to.

Without the .copy() method call on canvas, all the references in the code-FrameSequence point to *one* Picture, canvas. There is only *one* picture in the FrameSequence, and since, at the end, the canvas is in its final state, then all the references in FrameSeqence point to that same canvas Picture in its final state.



With the .copy() method call on canvas, you create *different* Picture instances for *each* reference in the FrameSequence. When we tell the FrameSequence to replay, the pictures referenced by the FrameSequence play out on the screen.



Exercises

1. Using sampled sounds and turtles, create a musical dance. Play music (sounds at least?) while the turtles move in patterns.

   - Your piece must last at least 10 seconds.
   - You must have at least five turtles. They can drop pictures, they can leave trails (or not), they can spin slowly, whatever you want them to do. Your turtles must move.
   - You must have at least four different sounds.
   - There must be some interweaving between turtle motion and sounds. In other words, you can't move the five turtles a little, then play 10 seconds of music. Hint: Use blockingPlay() instead of play() to play the sounds. If you use play(), the turtle movement and the sounds will go in parallel, which is nice, but you'll have no way to synchronize playing and moving. The method blockingPlay() will keep anything else from happening (e.g., turtle movement) during the playing of the sound.

   Implement your dance and sounds in a TurtleDance class in a main method.

   For extra credit, use MIDI (JMusic) instead of sampled sounds. Look up the Play object in the JMusic docs. Play.midi(score,**false**) will play a score in the background (**false** keeps it from quitting Java after playing). Play.waitcycle(score) will block (wait) anything else from happening until the score is done playing essentially, letting you block like blockingPlay().

5 Arrays: A Static Data Structure for Sounds

Chapter Learning Objectives

The last media type that we will need to create animations like those segments of the wildebeests and villagers is sampled sound. Sampled sound has an advantage for our purposes here—it's naturally an array. Sounds are arrays of samples. We will use sampled sounds to talk about the strengths and weaknesses of arrays as a data structure.

The computer science goals for this chapter are:

- To use and manipulate arrays, including insertions into the middle (shifting the rest towards the end) and deletions from the middle (shifting the end back and padding).

The media learning goals for this chapter are:

- To understand how sounds are sampled and stored on a computer.
- To learn methods for manipulating sounds.

5.1 Manipulating Sampled Sounds

We can work with sounds that come from WAV files. We sometimes call these *sampled sounds* because they are sounds made up of *samples* (thousands per second), in comparison with *MIDI music* which encodes music (notes, durations, instrument selections) but not the sounds themselves.

A sampled sound is a series of numbers (samples) that represent the air pressure at a given moment in time. As you probably know from your physics classes, sound is the result of vibrations in the air molecules around our ears. When the molecules bunch up, there is an increase in air pressure called *compression*; when the molecules then space back up, there is a *rarefaction* (a drop) in the air pressure. We can plot air pressure over time to see the cyles of sounds.

Each of these samples is a number that goes both positive (for increases in air pressure) and negative (for rarefactions). Typically, two *bytes* (8 bits each, for a total of 16 bits) are used to store each sample. Given that we

have to represent both negative and positive numbers in those 16 bits, we have plus or minus $32,000$ (roughly) as values in our samples. To capture all the frequencies of a sound that humans can hear, CD-quality sound requires that we capture $44,100$ samples every second.

A WAV file stores samples, albeit in a compressed form. MIDI actually stores specifications of music. MIDI files contain encoded commands of the form "Press down on this key now" and later "release that key now." What a "key" sounds like is determined by the MIDI synthesizer when the file is played. A WAV file, though, stores the original samples—the sound itself, as encoded on a computer.

Here's a simple example of creating a Sound instance from a file, and playing it.

```
> Sound s = new Sound(C:/cs1316/MediaSources/thisisatest.wav");
> s.play();
> s.increaseVolume(2.0);
> s.play();
```

How it works: Here we see us creating a new Sound instance (by saying **new** Sound). The *constructor* for the Sound class (the method that constructs and initializes a new instance of a class) takes a WAV filename as input, then creates a Sound instance from those samples. We play the sound using the play() method. We then increase the volume by 2.0 and play it again.

Increasing the volume is a matter of increasing the amplitude of the sound. Here's what that method looks like.

Program Example #21

Example Java Code: **Increase the volume of a sound by a factor**

```
/**
 * Increase the volume of a sound
 **/
public void increaseVolume(double factor){
  SoundSample [] samples = this.getSamples();
  SoundSample current = null;

  for (int i=0; i < samples.length; i++) {
    current = samples[i];
    current.setValue((int) (factor * current.getValue()));
  }
}
```

How it works: The first thing we do is to get all the samples out of the sound. getSamples() returns an array of SoundSample objects with all the

samples in the sound. We then use a **for** loop for the length of the samples. We get each sample, then multiply the factor times the current getValue() of the sample. We set the sample to the product. If the factor is less than 1.0, this reduces the volume, because the amplitude shrinks. If the factor is greater than 1.0, the sound increases in volume because the amplitude grows.

Just like with Picture instances, methods that *return* a new Sound are particularly powerful. Consider the following example:

```
> Sound s = new Sound("D:/cs1316/MediaSources/thisisatest.wav");
> s.play();
> s.reverse()
Sound number of samples: 64513
```

Why do you think we see this printout after reverse()? Because reverse doesn't *change* the Sound instance that it's called on—it returns a new one. If you were to execute s.play() right now, the sound would be the same. If you want to hear the reversed sound, you'd need to execute s.reverse().play();.

Here's how we reverse a sound.

Example Java Code: **Reversing a sound** *Program Example #22*

```
/**
 * Method to reverse a sound.
 **/
public Sound reverse()
{
  Sound target = new Sound(getLength());
  int sampleValue;

  for (int srcIndex=0,trgIndex=getLength()-1;
       srcIndex < getLength();
       srcIndex++,trgIndex--)
  {
    sampleValue = this.getSampleValueAt(srcIndex);
    target.setSampleValueAt(trgIndex,sampleValue);
  };
  return target;
}
```

How it works: The reverse() method first creates a target sound instance. It has the same length as the sound that reverse() is called upon. (Notice that a reference to getLength() without a specified object default to being references to **this**.) We use a **for** loop that manipulates two variables at

once. The source index, srcIndex goes up from 0 (the start of the array). The target index, trgIndex starts at the end of the list. Each time through the list, we add one to the source index and subtract one from the target index. The effect is to copy the front of the source to the back of the target, and to keep going until the whole sound is copied—reversing the sound. The methods getSampleValueAt and setSampleValueAt allow you to get and set the number in the sample. Most importantly, the last thing in the method is **return** target; which lets us meet the requirement of our method reverse() declaration, that it returns a Sound.

Debugging Tip: Beware the length as an index

Why did we subtract one from getLength to start out the target index (trgIndex)? Because getLength is the *number* of elements (samples) in the array, but the last *index* is getLength()−1. Computer scientists stubbornly insist on starting counting indices from zero, not one, so the last value is one less than the number of elements there.

Methods that return a new sound can then be used to create all kinds of interesting effects, without modifying the source sound.

```
> Sound s = new Sound(FileChooser.getMediaPath("gonga-2.wav"));
> Sound s2 = new Sound(FileChooser.getMediaPath("gongb-2.wav"));
> s.play();
> s2.play();
> s.reverse().play(); // Play first sound in reverse
> s.append(s2).play(); // Play first then second sound
> // Mix in the second sound, so you can hear part of each
> s.mix(s2,0.25).play();
> // Mix in the second sound sped up
> s.mix(s2.scale(0.5),0.25).play();
> s2.scale(0.5).play(); // Play the second sound sped up
> s2.scale(2.0).play(); // Play the second sound slowed down
> s.mix(s2.scale(2.0),0.25).play();
```

Given all of these, we can create a *collage* of sounds pretty easily.

Program Example #23

Example Java Code: **Create an audio collage**

```
public class MySoundCollage {
2
  public static void main(String [] args){
4
    Sound snap = new Sound(
6       FileChooser.getMediaPath("snap-tenth.wav"));
```

```
    Sound drum = new Sound(
8       FileChooser.getMediaPath("drumroll-1.wav"));
    Sound clink = new Sound(
10      FileChooser.getMediaPath("clink-tenth.wav"));
    Sound clap = new Sound(
12      FileChooser.getMediaPath("clap-q.wav"));

14  Sound drumRev = drum.reverse().scale(0.5);
    Sound soundA = snap.append(clink).
16      append(clink).append(clap).append(drumRev);
    Sound soundB = clink.append(clap).
18      append(clap).append(drum).append(snap).append(snap);

20  Sound collage = soundA.append(soundB).
        append(soundB).append(soundA).
22      append(soundA).append(soundB);
    collage.play();
24  }
}
```

Here is how some of these additional methods are coded.

Example Java Code: **Append one sound with another** *Program Example #24*

```
  /**
2  * Return this sound appended with the input sound
   * @param appendSound sound to append to this
4  **/
  public Sound append(Sound appendSound) {
6   Sound target = new Sound(getLength()+appendSound.getLength());
    int sampleValue;
8
    // Copy this sound in
10  for (int srcIndex=0,trgIndex=0;
         srcIndex < getLength();
12       srcIndex++,trgIndex++)
    {
14    sampleValue = this.getSampleValueAt(srcIndex);
      target.setSampleValueAt(trgIndex,sampleValue);
16  };

18  // Copy appendSound in to target
    for (int srcIndex=0,trgIndex=getLength();
20       srcIndex < appendSound.getLength();
         srcIndex++,trgIndex++)
```

```
22      {
          sampleValue = appendSound.getSampleValueAt(srcIndex);
24        target.setSampleValueAt(trgIndex,sampleValue);
        };
26
        return target;
28    }
```

Program Example #25

Example Java Code: **Mix in part of one sound with another**

```
    /**
2    * Mix the input sound with this sound, with percent ratio of input.
     * Use mixIn sound up to length of this sound.
4    * Return mixed sound.
     * @param mixIn sound to mix in
6    * @param ratio how much of input mixIn to mix in
     **/
8   public Sound mix(Sound mixIn, double ratio){
        Sound target = new Sound(getLength());
10
        int sampleValue, mixValue,newValue;
12
        // Copy this sound in
14      for (int srcIndex=0,trgIndex=0;
             srcIndex < getLength() && srcIndex < mixIn.getLength();
16           srcIndex++,trgIndex++)
        {
18        sampleValue = this.getSampleValueAt(srcIndex);
          mixValue = mixIn.getSampleValueAt(srcIndex);
20        newValue = (int)(ratio*mixValue) + (int)((1.0-ratio)*sampleValue);
          target.setSampleValueAt(trgIndex,newValue);
22      };
        return target;
24  }
```

Program Example #26

Example Java Code: **Scale a sound up or down in frequency**

```
    /**
2    * Scale up or down a sound by the given factor
     * (1.0 returns the same, 2.0 doubles the length, and 0.5 halves the length)
```

```
4     * @param factor ratio to increase or decrease
      **/
6   public Sound scale(double factor){
        Sound target = new Sound((int) (factor * (1+getLength())));
8       int sampleValue;

10      // Copy this sound in
        for (double srcIndex=0.0,trgIndex=0;
12           srcIndex < getLength();
             srcIndex+=(1/factor),trgIndex++)
14      {
          sampleValue = this.getSampleValueAt((int)srcIndex);
16        target.setSampleValueAt((int) trgIndex,sampleValue);
        };
18      return target;
    }
```

How it works: There are several tricky things going on in these methods, but not *too* many. Most of them are just copy loops with some tweak.

- The class Sound has a *constructor* that takes the number of *samples*.
- You'll notice in reverse that we can use $--$ as well as ++. variable$--$ is the same as variable = variable $-$ 1.
- In scale you'll see another shorthand that Java allows: srcIndex+=(1/factor) is the same as srcIndex = srcIndex + (1/factor).
- A **double** is a floating point number. These can't be automatically converted to integers. To use the results as integers where we need integers, we *cast* the result. We do that by putting the name of the class in parentheses before the result, e.g. (**int**) srcIndex.

5.2 Inserting and Deleting in an Array

A sound is naturally an array. It's a long list of sample values, one right after the other. Manipulation of sounds, then, gives us a sense of the tradeoffs of working with an array.

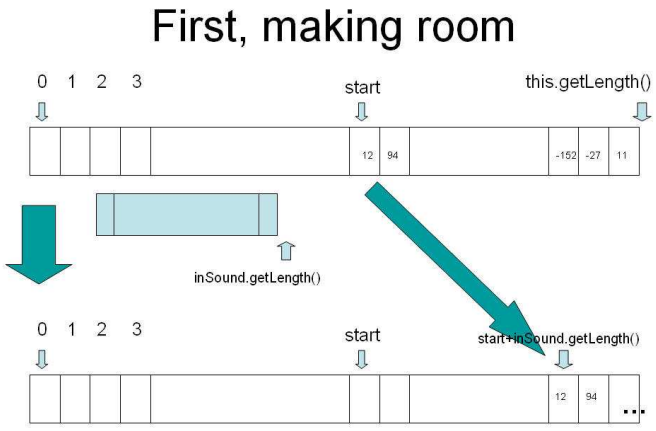
Imagine that you want to insert one sound *into* another—not overwriting parts of the original sound, but pushing the end further down. So if you had "This is a test" and you wanted to insert a *clink* sound after the word "is," you'd want to hear "This is*clink* a test." It might look like this:

```
> Sound test = new Sound("D:/cs1316/MediaSources/thisisatest.wav");
> test.getLength()
64513
> Sound clink = new Sound("D:/cs1316/MediaSources/clink-tenth.wav");
> clink.getLength()
```

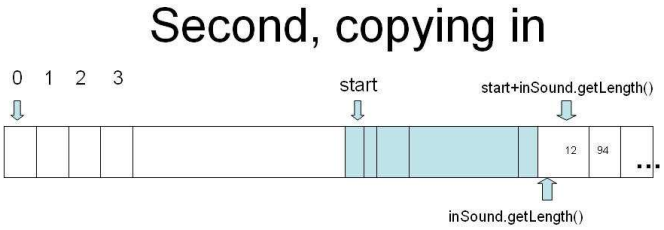
```
2184
> test.insertAfter(clink,40000)
> test.play()
```

How would you do this? Think about doing it physically. If you had a line of objects in particular spots (think about a line of mailboxes in an office) and you had to insert something in the middle, how would you do it? First thing you'd have to do is to make space for the new ones. You'd move the ones from the end further down. You would move the last ones first, and then the ones just before the old last, and then the ones before that—moving backwards towards the front. There are some error conditions to consider, e.g., what if there's not enough mailboxes? Assuming that you *have to* put in the new ones, you have to lose some of the old content. Maybe trim off the end?

In any case, your first step would look something like this:



And then, you would insert the new things in. That's the easy part.



That's essentially what it takes to do it with sounds, too.

Program Example #27

Example Java Code: **Inserting into the middle of sounds**

```
/**
 * insert the input Sound after the nth sample (input integer).
 * Modifies the given sound
 * @param insound Sound to insert
 * @param start index where to start inserting the new sound
 **/
public void insertAfter(Sound inSound, int start){

  SoundSample current=null;
  // Find how long insound is
  int amtToCopy = inSound.getLength();
  int endOfThis = this.getLength()-1;

  if (start + amtToCopy > endOfThis)
  {// If too long, copy only as much as will fit
    amtToCopy = endOfThis-start-1;}
  else {
    // If short enough, need to clear out room.
    // Copy from endOfThis-amtToCopy;, moving backwards
    // (toward front of list) to start,
    // moving UP (toward back) to endOfThis
    // KEY INSIGHT: How much gets lost off the end of the
    // array? Same size as what we're inserting -- amtToCopy
    for (int source=endOfThis-amtToCopy; source >= start ; source--)
    {
      // current is the TARGET -- where we're copying to
      current = this.getSample(source+amtToCopy);
      current.setValue(this.getSampleValueAt(source));
    }
  }

  // NOW, copy in inSound up to amtToCopy
  for (int target=start,source=0;
       source < amtToCopy;
       target++, source++) {
    current = this.getSample(target);
    current.setValue(inSound.getSampleValueAt(source));
  }
}
```

Think for a minute how long this takes to do. There are two loops here, and each one basically involves moving n elements, where n is the number of elements in the inserted array (sound). We would say that this algorithm is $O(2n)$ or $O(n)$. The number of operations grows linearly with the grown of the data.

Part II

Introducing Linked Lists

6 Structuring Music using Linked Lists

Chapter Learning Objectives

Media manipulators are often artists and always creative. They need flexibility in manipulating data, in inserting some here and deleting some there. Arrays, as we saw in the last chapter, are *not* particularly flexible. We will introduce *linked lists* in this chapter as a way of handling data more flexibly. In this chapter, the problem driving our exploration will be, "How do we make it easy for composers to creatively define music?"

The computer science goals for this chapter are:

- To create linked lists of various kinds.
- To understand and use operations on linked lists, including traversals, insertion, deletion, repetition, and weaving.
- To understand the tradeoffs between linked lists and arrays.
- To see a need for tree structures.

The media learning goals for this chapter are:

- To manipulate data flexibly.
- To develop different structures for composing MIDI creatively.
- To use rudimentary forms automated composition of music.

6.1 JMusic and Imports

Before you can use special features, those not built into the basic Java language, you have to **import** them.

Here's what it looks like when you run with the JMusic libraries installed (Figure 6.1):

```
Welcome to DrJava.
> import jm.music.data.*;
> import jm.JMC;
```

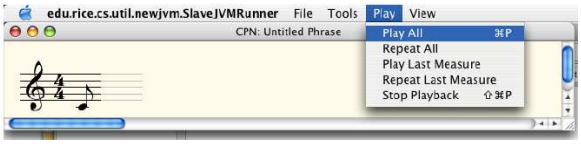


Figure 6.1: Playing all the notes in a score

```
> import jm.util.*;
> Note n = new Note(60,101);
> Note n = new Note(60,0.5); // Can't do this
Error: Redefinition of 'n'
> n=new Note(60,0.5);
> Phrase phr = new Phrase();
> phr.addNote(n);
> View.notate(phr);
```

The first argument to the *constructor* (the call to the class to create a new instance) for class Note is the *MIDI note*. Figure 6.2 shows the relation between frequencies, keys, and MIDI notes[1].

Here's another java that uses a different Phrase constructor to specify a starting time and an *instrument* which is also known as a *MIDI program*.

```
> import jm.music.data.*;
> import jm.JMC;
> import jm.util.*;
> Note n = new Note(60,0.5)
> Note n2 = new Note(JMC.C4,JMC.QN)
> Phrase phr = new Phrase(0.0,JMC.FLUTE);
> phr.addNote(n);
> phr.addNote(n2);
> View.notate(phr);
```

How it works:

- We import the pieces we need for Jmusic.
- We create a note using constants, then using named constants. JMC.C4 means "C in the 4th octave." JMC.QN means "quarter note." JMC is the class *Java Music Constants*, and it holds many important constants. The constant JMC.C4 means 60, like in the Table 2.1. A sharp would be noted like JMC.CS5 (C-sharp in the 5th octave). Eighth note is JMC.EN and half note is JMC.HN. A dotted eighth would be JMC.DEN.

[1]Taken from `http://www.phys.unsw.edu.au/~jw/notes.html`

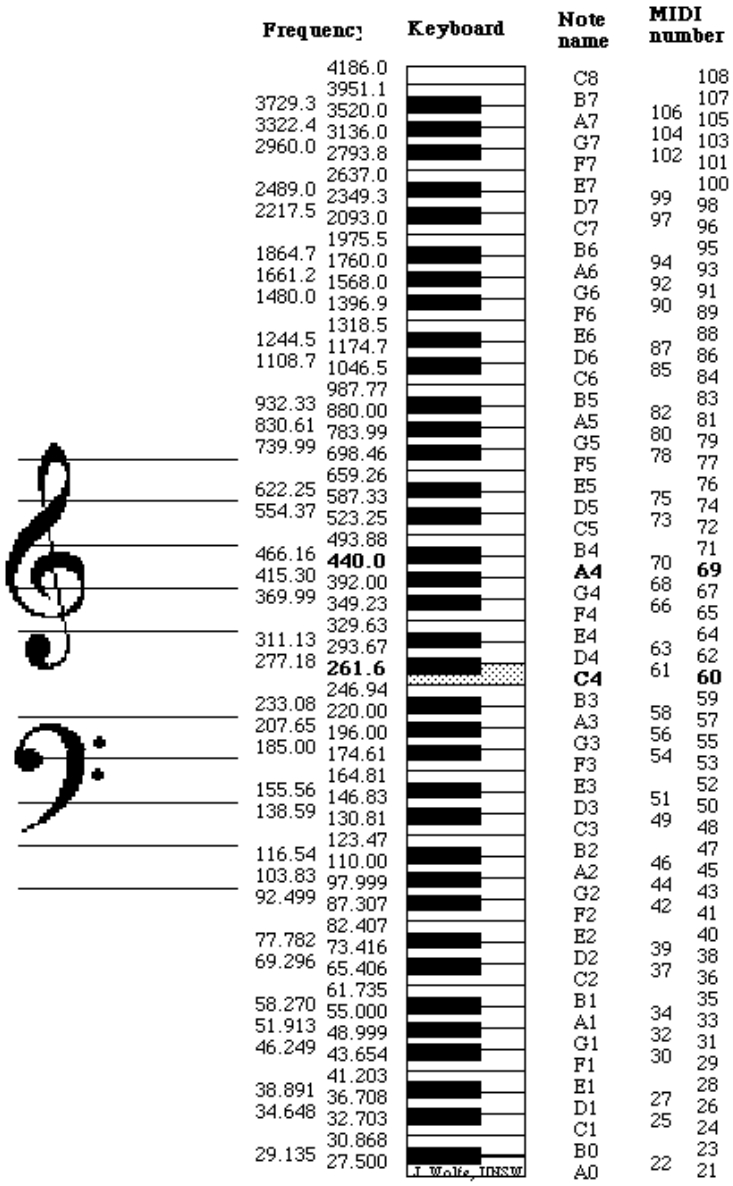

Figure 6.2: Frequencies, keys, and MIDI notes—-something I found on the Web that I need to recreate in a new way

- We create a Phrase object that starts at time 0.0 and uses the *instrument* JMC.FLUTE. JMC.FLUTE is a constant that corresponds to the correct instrument from Table 6.1.
- We put the notes into the Phrase instance, and then notate and view the whole phrase.

Piano	**Bass**	**Reed**	**Synth Effects**
0 — Acoustic Grand Piano	32 — Acoustic Bass	64 — Soprano Sax	96 — FX 1 (rain)
1 — Bright Acoustic Piano	33 — Electric Bass (finger)	65 — Alto Sax	97 — FX 2 (soundtrack)
2 — Electric Grand Piano	34 — Electric Bass (pick)	66 — Tenor Sax	98 — FX 3 (crystal)

	63 — Synth Brass 2	95 — Pad 8 (sweep)	127 — Gunshot

Table 6.1: MIDI Program numbers

We can create multiple parts with different start times and instruments. We want the different parts to map onto different *MIDI channels* if we want different start times and instruments (Figure 6.3). We'll need to combine the different parts into a Score object, which can then be viewed and notated the same way as we have with phrases and parts.

```
> Note n3=new Note(JMC.E4,JMC.EN)
> Note n4=new Note(JMC.G4,JMC.HN)
> Phrase phr2= new Phrase(0.5,JMC.PIANO);
> phr2.addNote(n3)
> phr2.addNote(n4)
> phr
-------- jMusic PHRASE: 'Untitled Phrase' contains 2 notes.  Start time: 0.0 -------
```

```
jMusic NOTE: [Pitch = 60][RhythmValue = 0.5][Dynamic = 85][Pan =
0.5][Duration = 0.45] jMusic NOTE: [Pitch = 60][RhythmValue =
1.0][Dynamic = 85][Pan = 0.5][Duration = 0.9]

> phr2
-------- jMusic PHRASE: 'Untitled Phrase' contains 2 notes.  Start time: 0.5 --------
jMusic NOTE: [Pitch = 64][RhythmValue = 0.5][Dynamic = 85][Pan =
0.5][Duration = 0.45] jMusic NOTE: [Pitch = 67][RhythmValue =
2.0][Dynamic = 85][Pan = 0.5][Duration = 1.8]

> Part partA = new Part(phr,"Part A",JMC.FLUTE,1)
> Part partB = new Part(phr2,"Part B",JMC.PIANO,2)
> Phrase phraseAB = new Phrase()
> Score scoreAB = new Score()
> scoreAB.addPart(partA)
> scoreAB.addPart(partB)
> View.notate(scoreAB)
```

Figure 6.3: Viewing a multipart score

How do you figure out what JMusic can do, what the classes are, and how to use them? There is a standard way of documenting Java classes called *Javadoc* which produces really useful documentation (Figure 6.4). JMusic is documented in this way. You can get to the JMusic Javadoc at `http://jmusic.ci.qut.edu.au/jmDocumentation/index.html`, or you can download it onto your own computer `http://jmusic.ci.qut.edu.au/GetjMusic.html`.

Table A.1 in the Appendix lists the constant names in JMC for accessing instrument names.

6.2 Starting out with JMusic

Here's what it looks like when you run:

```
Welcome to DrJava.
> import jm.music.data.*;
> import jm.JMC;
> import jm.util.*;
> Note n = new Note(C4,QUARTER_NOTE);
```

Figure 6.4: JMusic documention for the class Phrase

```
Error: Undefined class 'C4'
> Note n = new Note(60,QUARTER_NOTE);
Error: Undefined class 'QUARTER_NOTE'
> Note n = new Note(60,101);
> Note n = new Note(60,0.5);
Error: Redefinition of 'n'
> n=new Note(60,0.5);
> Phrase phr = new Phrase();
> phr.addNote(n);
> View.notate(phrase);
Error: Undefined class 'phrase'
> View.notate(phr);
```

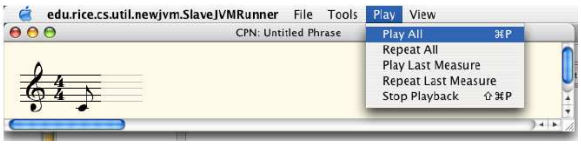

Figure 6.5: Playing all the notes in a score

6.3 Making a Simple Song Object

Program Example #28

Example Java Code: ***Amazing Grace* as a Song Object**

```
import jm.music.data.*;
import jm.JMC;
import jm.util.*;
import jm.music.tools.*;

public class AmazingGraceSong {
  private Score myScore = new Score("Amazing Grace");

  public void fillMeUp(){
    myScore.setTimeSignature(3,4);

   double[] phrase1data =
   {JMC.G4, JMC.QN,
     JMC.C5, JMC.HN, JMC.E5,JMC.EN, JMC.C5,JMC.EN,
     JMC.E5,JMC.HN,JMC.D5,JMC.QN,
     JMC.C5,JMC.HN,JMC.A4,JMC.QN,
     JMC.G4,JMC.HN,JMC.G4,JMC.EN,JMC.A4,JMC.EN,
     JMC.C5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
     JMC.E5,JMC.HN,JMC.D5,JMC.EN,JMC.E5,JMC.EN,
     JMC.G5,JMC.DHN};
   double[] phrase2data =
   {JMC.G5,JMC.HN,JMC.E5,JMC.EN,JMC.G5,JMC.EN,
     JMC.G5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
     JMC.E5,JMC.HN,JMC.D5,JMC.QN,
     JMC.C5,JMC.HN,JMC.A4,JMC.QN,
     JMC.G4,JMC.HN,JMC.G4,JMC.EN,JMC.A4,JMC.EN,
     JMC.C5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
     JMC.E5,JMC.HN,JMC.D5,JMC.QN,
     JMC.C5,JMC.DHN
   };
   Phrase myPhrase = new Phrase();
   myPhrase.addNoteList(phrase1data);
   myPhrase.addNoteList(phrase2data);
   //Mod.repeat(aPhrase, repeats);
   // create a new part and add the phrase to it
   Part aPart = new Part("Parts",
                         JMC.FLUTE, 1);
   aPart.addPhrase(myPhrase);
   // add the part to the score
   myScore.addPart(aPart);

  };

  public void showMe(){

   View.notate(myScore);
  };

}
```

* * *

How it works:

- We start with the **import** statements needed to use JMusic.
- We're declaring a new **class** whose name is AmazingGraceSong. It's **public** meaning that anyone can access it.
- There is a variable named myScore which is of type class Score. This means that the score myScore is duplicated in each instance of the class AmazingGraceSong. It's **private** because we don't actually want users of AmazingGraceSong messing with the score.
- There are two methods, fillMeUp and showMe. The first method fills the song with the right notes and durations (see the phrase data arrays in fillMeUp) with a flute playing the song. The second one opens it up for notation and playing.

  The phrase data arrays are named constants from the JMC class. They're in the order of note, duration, note, duration, and so on. The names actually all correspond to numbers, **double**s.

Using the program (Figure 6.6):

```
> AmazingGraceSong song1 = new AmazingGraceSong();
> song1.fillMeUp();
> song1.showMe();
```

6.4 Simple structuring of notes with an array

Let's start out grouping notes into arrays. We'll use Math.random() to generate random numbers between 0.0 and 1.0. We'll generate 100 random notes (Figure 6.7).

```
> import jm.util.*;
> import jm.music.data.*;
> Note [] somenotes = new Note[100];
> for (int i = 0; i<100; i++)
  { somenotes[i]=new Note((int)
        (128*Math.random()),0.25); }
> Phrase phr=new Phrase();
> for (int i= 0; i<100; i++)
   { phr.addNote(somenotes[i]); }
> View.notate(phr);
```

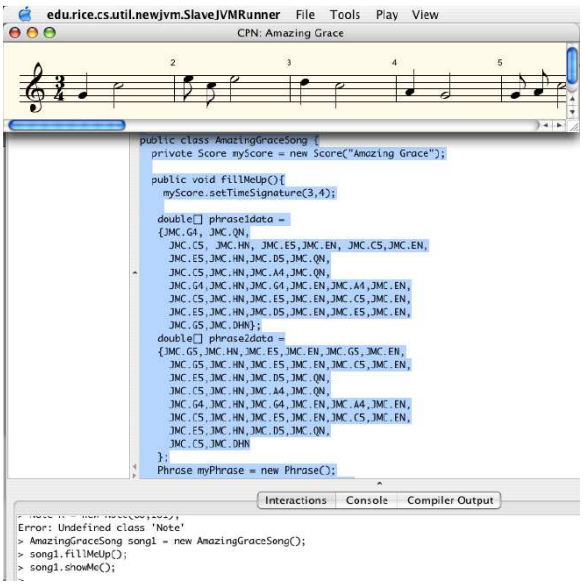

Figure 6.6: Trying the Amazing Grace song object

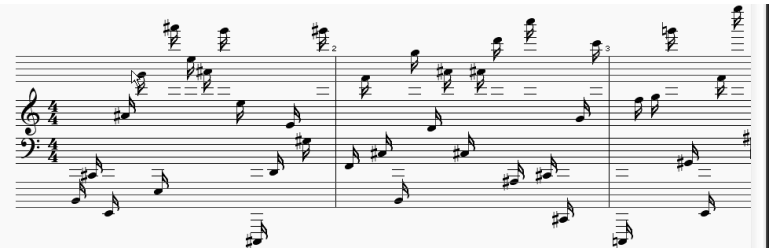

Figure 6.7: A hundred random notes

6.5 Making the Song Something to Explore

In a lot of ways AmazingGraceSong is a really lousy example–and not simply because it's a weak version of the tune. We can't really explore much with this version. What does it mean to have something that we can explore with?

How might one want to explore a song like this? We can come up with several ways, without even thinking much about it.

- How about changing the order of the pieces, or duplicating them? Maybe use a *Call and response* structure?
- How about using different instruments?

We did learn in an earlier chapter how to create songs with multiple parts. We can easily do multiple voice and multiple part *Amazing Grace*. Check out the below.

Program Example #29

Example Java Code: **Amazing Grace with Multiple Voices**

```
import jm.music.data.*;
import jm.JMC;
import jm.util.*;
import jm.music.tools.*;

public class MVAmazingGraceSong {
  private Score myScore = new Score("Amazing Grace");

  public Score getScore() {
    return myScore;
  };

  public void fillMeUp(){
    myScore.setTimeSignature(3,4);

   double[] phrase1data =
   {JMC.G4, JMC.QN,
     JMC.C5, JMC.HN, JMC.E5,JMC.EN, JMC.C5,JMC.EN,
     JMC.E5,JMC.HN,JMC.D5,JMC.QN,
     JMC.C5,JMC.HN,JMC.A4,JMC.QN,
     JMC.G4,JMC.HN,JMC.G4,JMC.EN,JMC.A4,JMC.EN,
     JMC.C5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
     JMC.E5,JMC.HN,JMC.D5,JMC.EN,JMC.E5,JMC.EN,
     JMC.G5,JMC.DHN};
   double[] phrase2data =
   {JMC.G5,JMC.HN,JMC.E5,JMC.EN,JMC.G5,JMC.EN,
     JMC.G5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
```

```
28        JMC.E5,JMC.HN,JMC.D5,JMC.QN,
          JMC.C5,JMC.HN,JMC.A4,JMC.QN,
30        JMC.G4,JMC.HN,JMC.G4,JMC.EN,JMC.A4,JMC.EN,
          JMC.C5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
32        JMC.E5,JMC.HN,JMC.D5,JMC.QN,
          JMC.C5,JMC.DHN
34      };

36      //
        Phrase trumpetPhrase = new Phrase();
38      trumpetPhrase.addNoteList(phrase1data); // 22.0 beats long
        double endphrase1 = trumpetPhrase.getEndTime();
40      System.out.println("End of phrase1:"+endphrase1);
        trumpetPhrase.addNoteList(phrase2data);
42      // create a new part and add the phrase to it
        Part part1 = new Part("TRUMPET PART",
44                            JMC.TRUMPET, 1);
        part1.addPhrase(trumpetPhrase);
46      // add the part to the score
        myScore.addPart(part1);
48      //
        Phrase flutePhrase = new Phrase(endphrase1);
50      flutePhrase.addNoteList(phrase1data); // 22.0 beats long
        flutePhrase.addNoteList(phrase2data); // optionally, remove this
52      // create a new part and add the phrase to it
        Part part2 = new Part("FLUTE PART",
54                            JMC.FLUTE, 2);
        part2.addPhrase(flutePhrase);
56      // add the part to the score
        myScore.addPart(part2);
58

60    };

62    public void showMe(){

64     View.notate(myScore);
      };
66
  }
```

We can use this program like this (Figure 6.8:

```
> MVAmazingGraceSong mysong = new MVAmazingGraceSong();
> song1.fillMeUp()
End of phrase1:22.0
> mysong.showMe();
```

How it works: The main idea that makes this program work is that we

Figure 6.8: Multi-voice *Amazing Grace* notation

create two phrases, one of which starts when first phrase (which is 22 beats long) ends. You'll note the use of System.out.println() which is a method that takes a string as input and prints it to the console. Parsing that method is probably a little challenging. There is a big object that has a lot of important objects as part of it called System. It includes a connection to the Interactions Pane called out. That connection (called a *stream*) knows how to print strings through the println (print line) method. The string concatenation operator, +, knows how to convert numbers into strings automatically.

But that's not a very satisfying example. Look at the fillMeUp method–that's pretty confusing stuff! What we do in the Interactions Pane doesn't give us much room to play around. The current structure doesn't lend itself to exploration.

How can we structure our program so that it's *easy* to explore, to try different things? How about if we start by thinking about how *expert musicians* think about music. They typically don't think about a piece of music as a single thing. Rather, they think about it in terms of a whole (a Score), parts (Part), and phrases (Phrase). They do think about these things in terms of a *sequence*–one part follows another. Each part will typically have its own notes (its own Phrase) and a starting time (sometimes parts start together, to get simultaneity, but at other times, will play after one another). Very importantly, there is an *ordering* to these parts. We can *model* that ordering by having each part know which other part comes next.

Let's try that in this next program.

Program Example #30

Example Java Code: **Amazing Grace as Song Elements**

```
import jm.music.data.*;
import jm.JMC;
import jm.util.*;
import jm.music.tools.*;
```

```
6  public class AmazingGraceSongElement {
     // Every element knows its next element and its part (of the score)
8    private AmazingGraceSongElement next;
     private Part myPart;
10
     // When we make a new element, the next part is empty, and ours is a blank new part
12   public AmazingGraceSongElement(){
       this.next = null;
14     this.myPart = new Part();
     }
16
     // addPhrase1 puts the first part of AmazingGrace into our part of the song
18   // at the desired start time with the given instrument
     public void addPhrase1(double startTime, int instrument){
20
      double[] phrase1data =
22    {JMC.G4, JMC.QN,
        JMC.C5, JMC.HN, JMC.E5,JMC.EN, JMC.C5,JMC.EN,
24      JMC.E5,JMC.HN,JMC.D5,JMC.QN,
        JMC.C5,JMC.HN,JMC.A4,JMC.QN,
26      JMC.G4,JMC.HN,JMC.G4,JMC.EN,JMC.A4,JMC.EN,
        JMC.C5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
28      JMC.E5,JMC.HN,JMC.D5,JMC.EN,JMC.E5,JMC.EN,
        JMC.G5,JMC.DHN};
30
         Phrase myPhrase = new Phrase(startTime);
32       myPhrase.addNoteList(phrase1data);
         this.myPart.addPhrase(myPhrase);
34       // In MVAmazingGraceSong, we did this when we initialized
         // the part. But we CAN do it later
36       this.myPart.setInstrument(instrument);
     }
38
     public void addPhrase2(double startTime, int instrument) {
40    double[] phrase2data =
      {JMC.G5,JMC.HN,JMC.E5,JMC.EN,JMC.G5,JMC.EN,
42      JMC.G5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
        JMC.E5,JMC.HN,JMC.D5,JMC.QN,
44      JMC.C5,JMC.HN,JMC.A4,JMC.QN,
        JMC.G4,JMC.HN,JMC.G4,JMC.EN,JMC.A4,JMC.EN,
46      JMC.C5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
        JMC.E5,JMC.HN,JMC.D5,JMC.QN,
48      JMC.C5,JMC.DHN
      };
50
         Phrase myPhrase = new Phrase(startTime);
52       myPhrase.addNoteList(phrase2data);
         this.myPart.addPhrase(myPhrase);
54       this.myPart.setInstrument(instrument);
```

```
  }
56
  // Here are the two methods needed to make a linked list of elements
58  public void setNext(AmazingGraceSongElement nextOne){
    this.next = nextOne;
60  }

62  public AmazingGraceSongElement next(){
    return this.next;
64  }

66  // We could just access myPart directly
  // but we can CONTROL access by using a method
68  // (called an accessor)
  // We'll use it in showFromMeOn
70  // (So maybe it doesn't need to be Public?)
  public Part part(){
72    return this.myPart;
  }
74
  // Why do we need this?
76  // If we want one piece to start after another, we need
  // to know when the last one ends.
78  // Notice: It's the phrase that knows the end time.
  //    We have to ask the part for its phrase (assuming only one)
80  //    to get the end time.
  public double getEndTime(){
82    return this.myPart.getPhrase(0).getEndTime();
  }
84
  // We need setChannel because each part has to be in its
86  // own channel if it has different start times.
  // So, we'll set the channel when we assemble the score.
88  // (But if we only need it for showFromMeOn, we could
  // make it PRIVATE...)
90  public void setChannel(int channel){
    myPart.setChannel(channel);
92  }

94  public void showFromMeOn(){
    // Make the score that we'll assemble the elements into
96    Score myScore = new Score("Amazing Grace");
      myScore.setTimeSignature(3,4);
98
      // Each element will be in its own channel
100   int channelCount = 1;

102   // Start from this element (this)
      AmazingGraceSongElement current = this;
104   // While we're not through...
```

```
      while (current != null)
106   {
        // Set the channel, increment the channel, then add it in.
108     current.setChannel(channelCount);
        channelCount = channelCount + 1;
110     myScore.addPart(current.part());

112     // Now, move on to the next element
        // which we already know isn't null
114     current = current.next();
      };
116
      // At the end, let's see it!
118   View.notate(myScore);

120 }

122 }
```

So, imagine that we want to play the first part as a flute, and the second part as a piano. Here's how we do it.

```
Welcome to DrJava.
> import jm.JMC;
> AmazingGraceSongElement part1 = new AmazingGraceSongElement();
> part1.addPhrase1(0.0,JMC.FLUTE);
> AmazingGraceSongElement part2 = new AmazingGraceSongElement();
> part2.addPhrase2(part1.getEndTime(),JMC.PIANO);
> part1.setNext(part2);
> part1.showFromMeOn()
```

That's an awful lot of extra effort just to do this, but here's the cool part. Let's do several other variations on *Amazing Grace* without writing any more programs. Say that you have a fondness for banjo, fiddle, and pipes for *Amazing Grace* (Figure 6.9).

```
> AmazingGraceSongElement banjo1 = new AmazingGraceSongElement();
> banjo1.addPhrase1(0.0,JMC.BANJO);
> AmazingGraceSongElement fiddle1=new AmazingGraceSongElement();
> fiddle1.addPhrase1(0.0,JMC.FIDDLE);
> banjo1.setNext(fiddle1);
> banjo1.getEndTime()
22.0
> AmazingGraceSongElement pipes2=new AmazingGraceSongElement();
> pipes2.addPhrase2(22.0,JMC.PIPES);
> fiddle1.setNext(pipes2);
> banjo1.showFromMeOn();
```

But now you're feeling that you want more of an orchestra feel. How about if we throw all of this together? That's easy. AmazingGraceSongElement part1

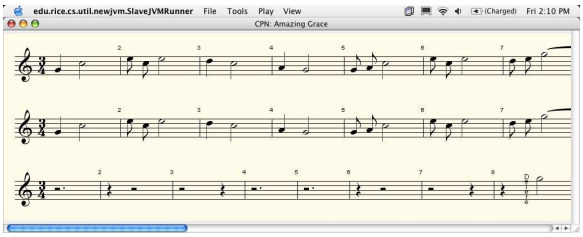

Figure 6.9: AmazingGraceSongElements with 3 pieces

is already linked to part2. AmazingGraceSongElement pipes1 isn't linked to anything. We'll just link part1 onto the end–very easy, to do a new experiment.

```
> pipes2.setNext(part1);
> banjo1.showFromMeOn();
```

Now we have a song with five pieces (Figure 6.10). "But wait," you might be thinking. "The ordering is all wrong!" Fortunately, the score figures it out for us. The starting times are all that's needed. The notion of a *next* element is just for our sake, to structure which pieces we want where.

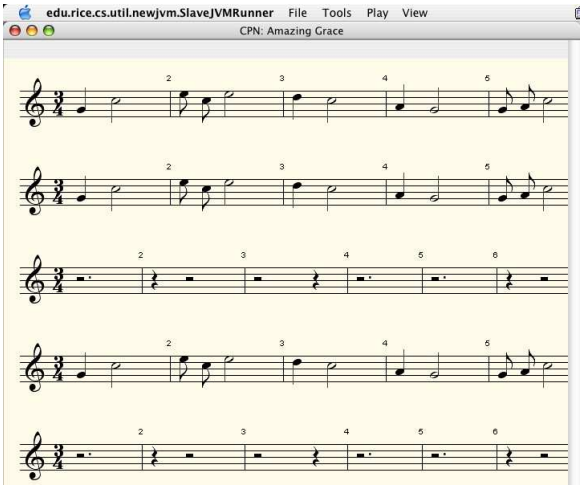

Figure 6.10: AmazingGraceSongElements with 3 pieces

At this point, you should be able to see how to play with lots of different pieces. What if you have a flute echo the pipes, just one beat behind? What

if you want to have several difference instruments playing the same thing, but one measure (three beats) behind the previous? Try them out!

Computer Science Idea: Layering software makes it easier to change
Notice that Phrase and Part has disappeared here. All that we're manipulating are song elements. A good layer allows you to ignore the layers below.

6.6 Making Any Song Something to Explore

What makes AmazingGraceSongElement something specific to the song *AmazingGrace*? It's really just those two addPhrase methods. Let's think about how we might generalize (abstract) these to make them usable to explore any song.

First, let's create a second version (cunningly called AmazingGraceSongElement2) where there is only one addPhrase method, but you decide which phrase you want as an input. We'll also clean up some of our protections here, while we're revising.

Example Java Code: **Amazing Grace as Song Elements, Take 2** *Program Example #31*

```
import jm.music.data.*;
import jm.JMC;
import jm.util.*;
import jm.music.tools.*;

public class AmazingGraceSongElement2 {
  // Every element knows its next element and its part (of the score)
  private AmazingGraceSongElement2 next;
  private Part myPart;

  // When we make a new element, the next part is empty, and ours is a blank new part
  public AmazingGraceSongElement2(){
    this.next = null;
    this.myPart = new Part();
  }

  // setPhrase takes a phrase and makes it the one for this element
  // at the desired start time with the given instrument
  public void setPhrase(Phrase myPhrase, double startTime, int instrument){

    //Phrases get returned from phrase1() and phrase2() with default (0.0) starTime
    // We can set it here with whatever setPhrase gets as input
```

```
      myPhrase.setStartTime(startTime);
24    this.myPart.addPhrase(myPhrase);
      // In MVAmazingGraceSong, we did this when we initialized
26    // the part. But we CAN do it later
      this.myPart.setInstrument(instrument);
28  }

30  // First phrase of Amazing Grace
    public Phrase phrase1() {
32      double[] phrase1data =
     {JMC.G4, JMC.QN,
34     JMC.C5, JMC.HN, JMC.E5,JMC.EN, JMC.C5,JMC.EN,
       JMC.E5,JMC.HN,JMC.D5,JMC.QN,
36     JMC.C5,JMC.HN,JMC.A4,JMC.QN,
       JMC.G4,JMC.HN,JMC.G4,JMC.EN,JMC.A4,JMC.EN,
38     JMC.C5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
       JMC.E5,JMC.HN,JMC.D5,JMC.EN,JMC.E5,JMC.EN,
40     JMC.G5,JMC.DHN};

42      Phrase myPhrase = new Phrase();
        myPhrase.addNoteList(phrase1data);
44      return myPhrase;
    }
46
    public Phrase phrase2() {
48    double[] phrase2data =
     {JMC.G5,JMC.HN,JMC.E5,JMC.EN,JMC.G5,JMC.EN,
50     JMC.G5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
       JMC.E5,JMC.HN,JMC.D5,JMC.QN,
52     JMC.C5,JMC.HN,JMC.A4,JMC.QN,
       JMC.G4,JMC.HN,JMC.G4,JMC.EN,JMC.A4,JMC.EN,
54     JMC.C5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
       JMC.E5,JMC.HN,JMC.D5,JMC.QN,
56     JMC.C5,JMC.DHN
      };
58
        Phrase myPhrase = new Phrase();
60      myPhrase.addNoteList(phrase2data);
        return myPhrase;
62  }

64  // Here are the two methods needed to make a linked list of elements
    public void setNext(AmazingGraceSongElement2 nextOne){
66    this.next = nextOne;
    }
68
    public AmazingGraceSongElement2 next(){
70    return this.next;
    }
72
```

```
    // We could just access myPart directly
74  // but we can CONTROL access by using a method
    // (called an accessor)
76  private Part part(){
      return this.myPart;
78  }

80  // Why do we need this?
    // If we want one piece to start after another, we need
82  // to know when the last one ends.
    // Notice: It's the phrase that knows the end time.
84  //    We have to ask the part for its phrase (assuming only one)
    //    to get the end time.
86  public double getEndTime(){
      return this.myPart.getPhrase(0).getEndTime();
88  }

90  // We need setChannel because each part has to be in its
    // own channel if it has different start times.
92  // So, we'll set the channel when we assemble the score.
    private void setChannel(int channel){
94    myPart.setChannel(channel);
    }
96
    public void showFromMeOn(){
98    // Make the score that we'll assemble the elements into
      // We'll set it up with the time signature and tempo we like
100     Score myScore = new Score("Amazing Grace");
        myScore.setTimeSignature(3,4);
102     myScore.setTempo(120.0);

104     // Each element will be in its own channel
        int channelCount = 1;
106
        // Start from this element (this)
108     AmazingGraceSongElement2 current = this;
        // While we're not through...
110     while (current != null)
        {
112       // Set the channel, increment the channel, then add it in.
          current.setChannel(channelCount);
114       channelCount = channelCount + 1;
          myScore.addPart(current.part());
116
          // Now, move on to the next element
118       // which we already know isn't null
          current = current.next();
120     };

122     // At the end, let's see it!
```

```
        View.notate(myScore);
124
    }
126
}
```

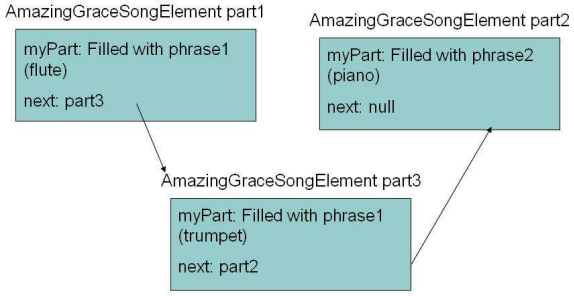
We can use this to do the flute for the first part and a piano for the second in much the same way as we did last time.

```
> import jm.JMC;
> AmazingGraceSongElement2 part1 = new AmazingGraceSongElement2();
> part1.setPhrase(part1.phrase1(),0.0,JMC.FLUTE);
> AmazingGraceSongElement2 part2 = new AmazingGraceSongElement2();
> part2.setPhrase(part2.phrase2(),22.0,JMC.PIANO);
> part1.setNext(part2);
> part1.showFromMeOn();
```

Let's go one step further, then make sure we understand what showFromMeOn is doing.

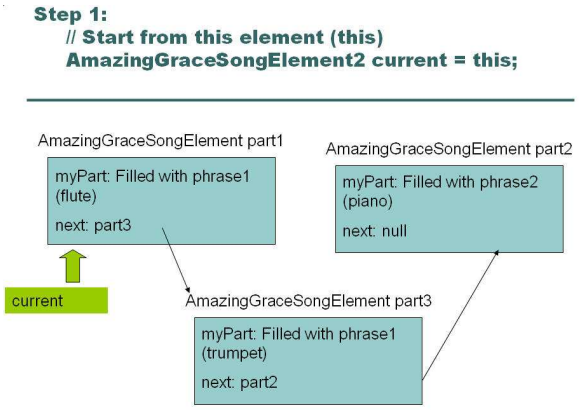
```
> AmazingGraceSongElement2 part3 = new AmazingGraceSongElement2();
> part3.setPhrase(part3.phrase1(),0.0, JMC.TRUMPET);
> part1.setNext(part3);
> part3.setNext(part2);
> part1.showFromMeOn();
```

How it works: What we are doing here is to create a new part, part3, and to insert it *between* part1 and part2. We might think of the result as looking like this.

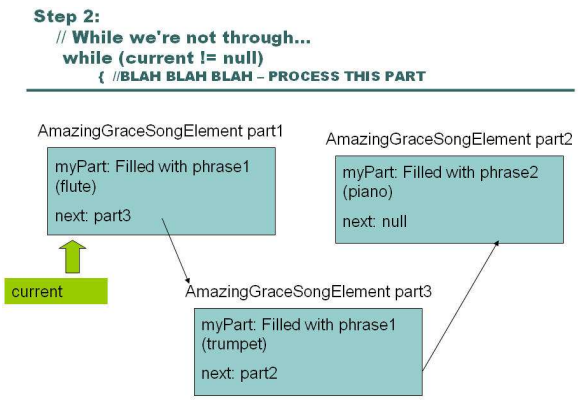


What is happening when we execute part1.showFromMeOn()? Let's trace it slowly.

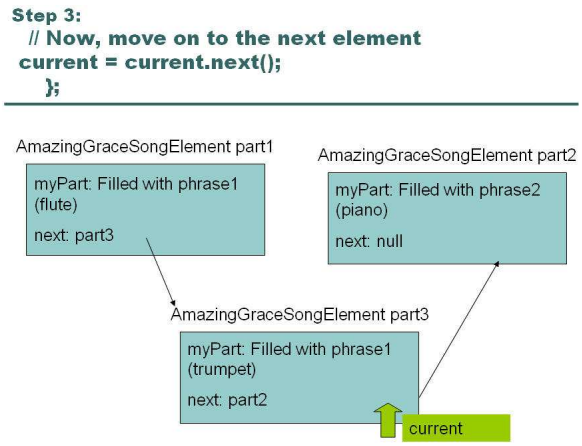
- First, we start out with current pointing at **this**, which is our part1. I like to think about traversing a linked list as being like pulling myself hand-over-hand on a ladder. Your right hand is current, and it's now holding on to the node1 rung of the ladder.



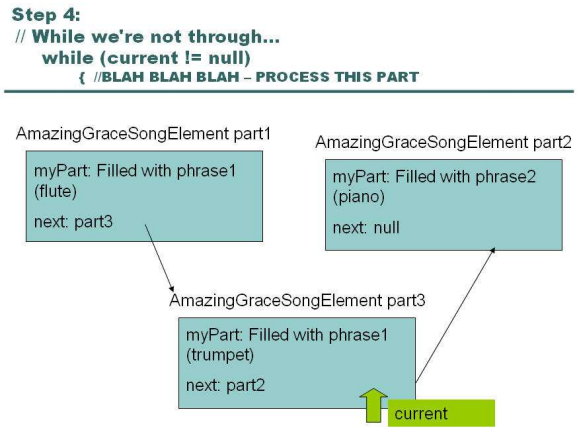
- Since current is not null (our right hand is holding something), we go ahead and process it.



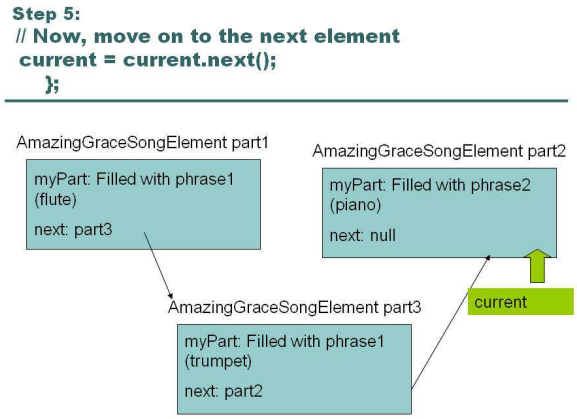
- We now feel out with our left hand for the rung connected to our current rung—that is a way of thinking about what current.next() is doing. Once we find the next rung with our left hand, we grab it with our right hand. We now have a new current node to process.



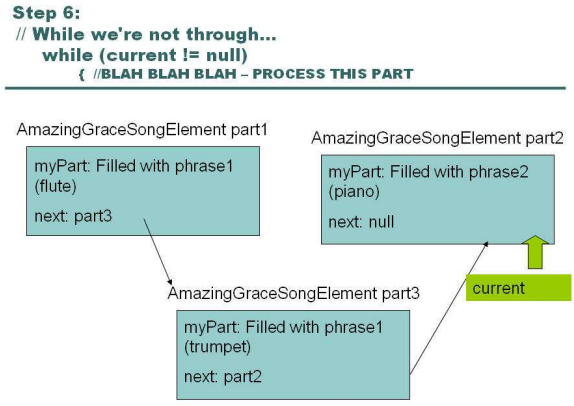
- This one isn't null either, so we process it.



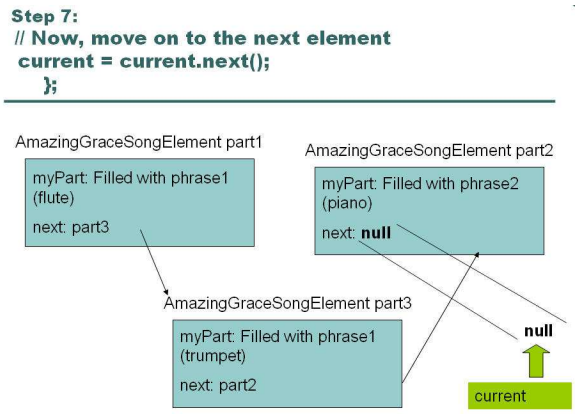
- Moving our left hand out to the next rung, then grabbing that new rung with our right, we have a new current node to process.



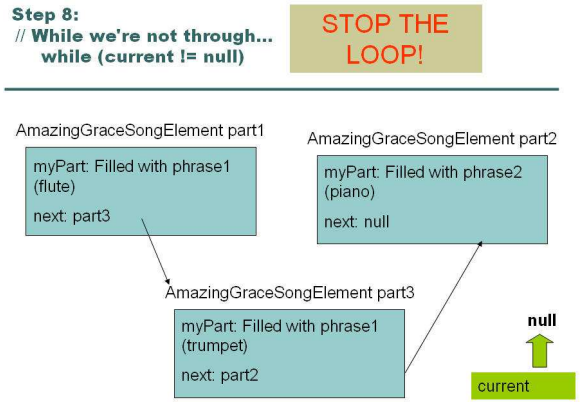
- Still not null, so let's process it.



- Now we reach out again with our left hand and find...nothing! We grab that nothing (**null**) with our right hand now, too. We're past the end of the ladder, er, linked list!



- We check at the top of the loop—yup, we're done.



Now let's make a few observations about this code. Notice the part2.phrase2() expression. What would have happened if we did part1.phrase2() there instead? Would it have worked? (Go ahead, try it. We'll wait.) It would because both objects know the same phrase1() and phrase2() methods.

That doesn't really make a lot of sense, does it, in terms of what each object should know? Does every song element object need to know how to make every other song elements' phrase? We can get around this by creating a **static** method. Static methods are known to the **class**, not to the individual objects (*instances*). We'd write it something like this:

```
// First phrase of Amazing Grace
static public Phrase phrase1() {
    double[] phrase1data =
 {JMC.G4, JMC.QN,
   JMC.C5, JMC.HN, JMC.E5,JMC.EN, JMC.C5,JMC.EN,
   JMC.E5,JMC.HN,JMC.D5,JMC.QN,
   JMC.C5,JMC.HN,JMC.A4,JMC.QN,
```

```
      JMC.G4,JMC.HN,JMC.G4,JMC.EN,JMC.A4,JMC.EN,
      JMC.C5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
      JMC.E5,JMC.HN,JMC.D5,JMC.EN,JMC.E5,JMC.EN,
      JMC.G5,JMC.DHN};

      Phrase myPhrase = new Phrase();
      myPhrase.addNoteList(phrase1data);
      return myPhrase;
  }
```

We'd actually use this method like this:

```
> import jm.JMC;
> AmazingGraceSongElement2 part1 = new AmazingGraceSongElement2();
> part1.setPhrase(AmazingGraceSongElement2.phrase1(),0.0,JMC.FLUTE);
```

Now, that makes sense in an object-oriented kind of way: it's the *class AmazingGraceSongElement2* that knows about the phrases in the song *Amazing Grace*, not the instances of the class–not the different elements. But it's not really obvious that it's important for this to be about *Amazing Grace* at all! Wouldn't *any* song elements have basically this structure? Couldn't these phrases (now that they're in static methods) go in *any* class?

Generalizing SongElement and SongPhrase

Let's make a *generic* SongElement class, and a new class SongPhrase that we could stuff lots of phrases in.

Example Java Code: **General Song Elements and Song Phrases** *Program Example #32*

```
import jm.music.data.*;
import jm.JMC;
import jm.util.*;
import jm.music.tools.*;

public class SongElement {
  // Every element knows its next element and its part (of the score)
  private SongElement next;
  private Part myPart;

  // When we make a new element, the next part is empty, and ours is a blank new part
  public SongElement(){
    this.next = null;
    this.myPart = new Part();
  }

  // setPhrase takes a phrase and makes it the one for this element
  // at the desired start time with the given instrument
```

```
    public void setPhrase(Phrase myPhrase, double startTime, int instrument){
20      myPhrase.setStartTime(startTime);
        this.myPart.addPhrase(myPhrase);
22      this.myPart.setInstrument(instrument);
    }
24

26  // Here are the two methods needed to make a linked list of elements
    public void setNext(SongElement nextOne){
28      this.next = nextOne;
    }
30
    public SongElement next(){
32      return this.next;
    }
34
    // We could just access myPart directly
36  // but we can CONTROL access by using a method
    // (called an accessor)
38  private Part part(){
      return this.myPart;
40  }

42  // Why do we need this?
    // If we want one piece to start after another, we need
44  // to know when the last one ends.
    // Notice: It's the phrase that knows the end time.
46  //    We have to ask the part for its phrase (assuming only one)
    //    to get the end time.
48  public double getEndTime(){
      return this.myPart.getPhrase(0).getEndTime();
50  }

52  // We need setChannel because each part has to be in its
    // own channel if it has different start times.
54  // So, we'll set the channel when we assemble the score.
    private void setChannel(int channel){
56    myPart.setChannel(channel);
    }
58
    public void showFromMeOn(){
60    // Make the score that we'll assemble the elements into
      // We'll set it up with a default time signature and tempo we like
62    // (Should probably make it possible to change these — maybe with inputs?)
       Score myScore = new Score("My Song");
64     myScore.setTimeSignature(3,4);
       myScore.setTempo(120.0);
66
       // Each element will be in its own channel
68     int channelCount = 1;
```

```
70        // Start from this element (this)
          SongElement current = this;
72        // While we're not through...
          while (current != null)
74        {
            // Set the channel, increment the channel, then add it in.
76          current.setChannel(channelCount);
            channelCount = channelCount + 1;
78          myScore.addPart(current.part());

80          // Now, move on to the next element
            // which we already know isn't null
82          current = current.next();
          };
84
          // At the end, let's see it!
86        View.notate(myScore);

88    }

90  }
```

```
  import jm.music.data.*;
2 import jm.JMC;
  import jm.util.*;
4 import jm.music.tools.*;

6 public class SongPhrase {

8   // First phrase of Amazing Grace
    static public Phrase AG1() {
10      double[] phrase1data =
     {JMC.G4, JMC.QN,
12     JMC.C5, JMC.HN, JMC.E5,JMC.EN, JMC.C5,JMC.EN,
       JMC.E5,JMC.HN,JMC.D5,JMC.QN,
14     JMC.C5,JMC.HN,JMC.A4,JMC.QN,
       JMC.G4,JMC.HN,JMC.G4,JMC.EN,JMC.A4,JMC.EN,
16     JMC.C5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
       JMC.E5,JMC.HN,JMC.D5,JMC.EN,JMC.E5,JMC.EN,
18     JMC.G5,JMC.DHN};

20      Phrase myPhrase = new Phrase();
        myPhrase.addNoteList(phrase1data);
22      return myPhrase;
    }
24  // Second phrase of Amazing Grace
    static public Phrase AG2() {
26    double[] phrase2data =
     {JMC.G5,JMC.HN,JMC.E5,JMC.EN,JMC.G5,JMC.EN,
```

```
28        JMC.G5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
          JMC.E5,JMC.HN,JMC.D5,JMC.QN,
30        JMC.C5,JMC.HN,JMC.A4,JMC.QN,
          JMC.G4,JMC.HN,JMC.G4,JMC.EN,JMC.A4,JMC.EN,
32        JMC.C5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
          JMC.E5,JMC.HN,JMC.D5,JMC.QN,
34        JMC.C5,JMC.DHN
       };
36
          Phrase myPhrase = new Phrase();
38        myPhrase.addNoteList(phrase2data);
          return myPhrase;
40    }

42  }
```

We can use this like this:

```
> import jm.JMC;
> SongElement part1 = new SongElement();
> part1.setPhrase(SongPhrase.AG1(),0.0,JMC.FLUTE);
> SongElement part2 = new SongElement();
> part2.setPhrase(SongPhrase.AG2(),22.0,JMC.PIANO);
> part1.setNext(part2);
> part1.showFromMeOn();
```

We now have a structure to do more songs and more general explorations.

Adding More Phrases

Program Example #33

Example Java Code: **More phrases to play with**

```
import jm.music.data.*;
2 import jm.JMC;
  import jm.util.*;
4 import jm.music.tools.*;

6 public class SongPhrase {

8   // First phrase of Amazing Grace
    static public Phrase AG1() {
10      double[] phrase1data =
    {JMC.G4, JMC.QN,
12    JMC.C5, JMC.HN, JMC.E5,JMC.EN, JMC.C5,JMC.EN,
```

```
        JMC.E5,JMC.HN,JMC.D5,JMC.QN,
14      JMC.C5,JMC.HN,JMC.A4,JMC.QN,
        JMC.G4,JMC.HN,JMC.G4,JMC.EN,JMC.A4,JMC.EN,
16      JMC.C5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
        JMC.E5,JMC.HN,JMC.D5,JMC.EN,JMC.E5,JMC.EN,
18      JMC.G5,JMC.DHN};

20        Phrase myPhrase = new Phrase();
          myPhrase.addNoteList(phrase1data);
22        return myPhrase;
    }
24  // Second phrase of Amazing Grace
    static public Phrase AG2() {
26    double[] phrase2data =
     {JMC.G5,JMC.HN,JMC.E5,JMC.EN,JMC.G5,JMC.EN,
28      JMC.G5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
        JMC.E5,JMC.HN,JMC.D5,JMC.QN,
30      JMC.C5,JMC.HN,JMC.A4,JMC.QN,
        JMC.G4,JMC.HN,JMC.G4,JMC.EN,JMC.A4,JMC.EN,
32      JMC.C5,JMC.HN,JMC.E5,JMC.EN,JMC.C5,JMC.EN,
        JMC.E5,JMC.HN,JMC.D5,JMC.QN,
34      JMC.C5,JMC.DHN
     };
36
          Phrase myPhrase = new Phrase();
38        myPhrase.addNoteList(phrase2data);
          return myPhrase;
40  }

42  // House of the rising sun
    static public Phrase house(){
44    double [] phrasedata =
      {JMC.E4,JMC.EN,JMC.A3,JMC.HN,JMC.B3,JMC.EN,JMC.A3,JMC.EN,
46      JMC.C4,JMC.HN,JMC.D4,JMC.EN,JMC.DS4,JMC.EN,
        JMC.E4,JMC.HN,JMC.C4,JMC.EN,JMC.B3,JMC.EN,
48      JMC.A3,JMC.HN,JMC.E4,JMC.QN,
        JMC.A4,JMC.HN, JMC.E4, JMC.QN,
50      JMC.G4,JMC.HN, JMC.E4,JMC.EN,JMC.D4,JMC.EN,JMC.E4,JMC.DHN,
        JMC.E4,JMC.HN,JMC.GS4,JMC.EN,JMC.G4,JMC.EN,
52      JMC.A4,JMC.HN,JMC.A3,JMC.QN,
        JMC.C4,JMC.EN,JMC.C4,JMC.DQN,JMC.E4,JMC.QN,
54      JMC.E4,JMC.EN,JMC.E4,JMC.EN,JMC.E4,JMC.QN,JMC.C4,JMC.EN,JMC.B3,JMC.EN,
        JMC.A3,JMC.HN,JMC.E4,JMC.QN,
56      JMC.E4,JMC.HN,JMC.E4,JMC.EN,
        JMC.E4,JMC.EN,JMC.G3,JMC.QN,JMC.C4,JMC.EN,JMC.B3,JMC.EN,
58      JMC.A3,JMC.DHN};

60        Phrase myPhrase = new Phrase();
          myPhrase.addNoteList(phrasedata);
62        return myPhrase;
```

```
    }
64
     //Little Riff1
66    static public Phrase riff1() {
       double[] phrasedata =
68    {JMC.G3,JMC.EN,JMC.B3,JMC.EN,JMC.C4,JMC.EN,JMC.D4,JMC.EN};

70       Phrase myPhrase = new Phrase();
         myPhrase.addNoteList(phrasedata);
72       return myPhrase;
    }
74
       //Little Riff2
76    static public Phrase riff2() {
       double[] phrasedata =
78    {JMC.D4,JMC.EN,JMC.C4,JMC.EN,JMC.E4,JMC.EN,JMC.G4,JMC.EN};

80       Phrase myPhrase = new Phrase();
         myPhrase.addNoteList(phrasedata);
82       return myPhrase;
    }
84

86    //Little Riff3
      static public Phrase riff3() {
88     double[] phrasedata =
      {JMC.C4,JMC.QN,JMC.E4,JMC.EN,JMC.G4,JMC.EN,JMC.E4,JMC.SN,
90       JMC.G4,JMC.SN,JMC.E4,JMC.SN,JMC.G4,JMC.SN,JMC.C4,JMC.QN};

92       Phrase myPhrase = new Phrase();
         myPhrase.addNoteList(phrasedata);
94       return myPhrase;
    }
96
      //Little Riff4
98    static public Phrase riff4() {
       double[] phrasedata =
100   {JMC.C4,JMC.QN,JMC.E4,JMC.QN,JMC.G4,JMC.QN,JMC.C4,JMC.QN};

102      Phrase myPhrase = new Phrase();
         myPhrase.addNoteList(phrasedata);
104      return myPhrase;
    }
106

108 }
```

* * *

```
> SongElement house = new SongElement();
> house.setPhrase(SongPhrase.house(),0.0,JMC.HARMONICA);
> house.showFromMeOn();

> SongElement riff1 = new SongElement();
> riff1.setPhrase(SongPhrase.riff1(),0.0,JMC.HARMONICA);
> riff1.showFromMeOn();
> SongElement riff2 = new SongElement();
> riff2.setPhrase(SongPhrase.riff2(),0.0,JMC.TENOR_SAX);
> riff2.showFromMeOn();
```

But music is really about repetition and playing off pieces and variations. Try something like this (Figure 6.11).

```
> SongElement riff1 = new SongElement();
> riff1.setPhrase(SongPhrase.riff1(),0.0,JMC.HARMONICA);
> riff1.showFromMeOn();
-- Constructing MIDI file from'My Song'... Playing with JavaSound ... Completed MIDI playback
> SongElement riff2 = new SongElement();
> riff2.setPhrase(SongPhrase.riff2(),0.0,JMC.TENOR_SAX);
> riff2.showFromMeOn();
-- Constructing MIDI file from'My Song'... Playing with JavaSound ... Completed MIDI playback
> riff2.getEndTime()
2.0
> SongElement riff4 = new SongElement();
> riff4.setPhrase(SongPhrase.riff1(),2.0,JMC.TENOR_SAX);
> SongElement riff5 = new SongElement();
> riff5.setPhrase(SongPhrase.riff1(),4.0,JMC.TENOR_SAX);
> SongElement riff6 = new SongElement();
> riff6.setPhrase(SongPhrase.riff2(),4.0,JMC.HARMONICA);
> SongElement riff7 = new SongElement();
> riff7.setPhrase(SongPhrase.riff1(),6.0,JMC.JAZZ_GUITAR);
> riff1.setNext(riff2);
> riff2.setNext(riff4);
> riff4.setNext(riff5);
> riff5.setNext(riff6);
> riff6.setNext(riff7);
> riff1.showFromMeOn();
```

Computing phrases

If we need some repetition, we don't have to type things over and over again–we can ask the computer to do it for us! Our phrases in **class** SongPhrase don't have to come from constants. It's okay if they are computed phrases.

We can use steel drums (or something else, if we want) to create rhythm.

```
> SongElement steel = new SongElement();
> steel.setPhrase(SongPhrase.riff1(),0.0,JMC.STEEL_DRUM);
> steel.showFromMeOn();
```

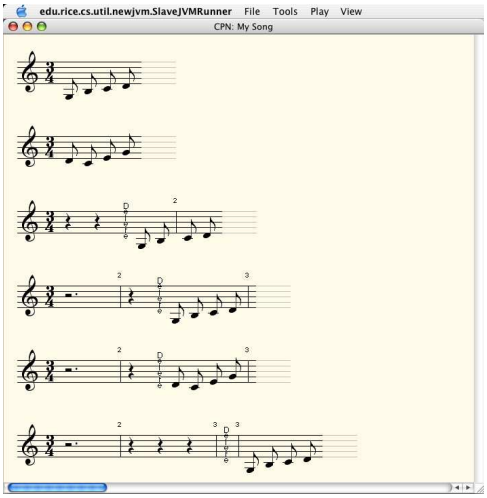


Figure 6.11: Playing some different riffs in patterns

Program Example #34

Example Java Code: **Computed Phrases**

```
//Larger Riff1
static public Phrase pattern1() {
      double[] riff1data =
{JMC.G3,JMC.EN,JMC.B3,JMC.EN,JMC.C4,JMC.EN,JMC.D4,JMC.EN};
 double[] riff2data =
{JMC.D4,JMC.EN,JMC.C4,JMC.EN,JMC.E4,JMC.EN,JMC.G4,JMC.EN};

 int counter1;
 int counter2;

 Phrase myPhrase = new Phrase();
 // 3 of riff1, 1 of riff2, and repeat all of it 3 times
 for (counter1 = 1; counter1 <= 3; counter1++)
 {for (counter2 = 1; counter2 <= 3; counter2++)
   myPhrase.addNoteList(riff1data);
 myPhrase.addNoteList(riff2data);
 };
   return myPhrase;
}

   //Larger Riff2
```

```
    static public Phrase pattern2() {
          double[] riff1data =
    {JMC.G3,JMC.EN,JMC.B3,JMC.EN,JMC.C4,JMC.EN,JMC.D4,JMC.EN};
     double[] riff2data =
    {JMC.D4,JMC.EN,JMC.C4,JMC.EN,JMC.E4,JMC.EN,JMC.G4,JMC.EN};

     int counter1;
     int counter2;

     Phrase myPhrase = new Phrase();
     // 2 of riff1, 2 of riff2, and repeat all of it 3 times
     for (counter1 = 1; counter1 <= 3; counter1++)
     {for (counter2 = 1; counter2 <= 2; counter2++)
       myPhrase.addNoteList(riff1data);
     for (counter2 = 1; counter2 <= 2; counter2++)
       myPhrase.addNoteList(riff2data);
     };
       return myPhrase;
    }

    //Rhythm Riff
    static public Phrase rhythm1() {
          double[] riff1data =
    {JMC.G3,JMC.EN,JMC.REST,JMC.HN,JMC.D4,JMC.EN};
     double[] riff2data =
    {JMC.C3,JMC.QN,JMC.REST,JMC.QN};

     int counter1;
     int counter2;

     Phrase myPhrase = new Phrase();
     // 2 of rhythm riff1, 2 of rhythm riff2, and repeat all of it 3 times
     for (counter1 = 1; counter1 <= 3; counter1++)
     {for (counter2 = 1; counter2 <= 2; counter2++)
       myPhrase.addNoteList(riff1data);
     for (counter2 = 1; counter2 <= 2; counter2++)
       myPhrase.addNoteList(riff2data);
     };
       return myPhrase;
    }
```

```
   > import jm.JMC;
> SongElement sax1 = new SongElement();
> sax1.setPhrase(SongPhrase.pattern1(),0.0,JMC.TENOR_SAX);
> sax1.showFromMeOn();
-- Constructing MIDI file from'My Song'... Playing with JavaSound ... Completed MIDI playback
> SongElement sax2 = new SongElement();
> sax2.setPhrase(SongPhrase.pattern2(),0.0,JMC.TENOR_SAX);
```

```
> sax2.showFromMeOn()
-- Constructing MIDI file from'My Song'... Playing with JavaSound ... Completed MIDI
> sax1.setNext(sax2);
> sax1.showFromMeOn();
-- Constructing MIDI file from'My Song'... Playing with JavaSound ... Completed MIDI
> sax1.setNext(null);  // I decided I didn't like it.
> SongElement rhythm1=new SongElement();
> rhythm1.setPhrase(SongPhrase.rhythm1(),0.0,JMC.STEEL_DRUM);
> sax1.setNext(rhythm1); // I put something else with the sax
> sax1.showFromMeOn();
-- Constructing MIDI file from'My Song'... Playing with JavaSound ... Completed MIDI
```

Here's what the sax plus rhythm looked like (Figure 6.12).

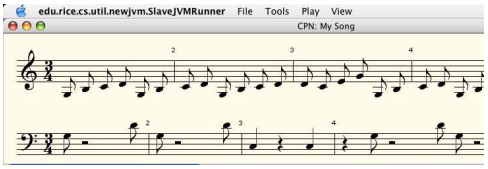

Figure 6.12: Sax line in the top part, rhythm in the bottom

Computer Science Idea: Layering software makes it easier to change, Part 2

Notice that all our Editor Pane interactions now are with SongPhrase. We don't have to change SongElements anymore–they work, so now we can ignore them. We're not dealing with Phrases and Parts anymore, either. As we develop layers, if we do it right, we only have to deal with one layer at a time (Figure 6.13).

If we're computing phrases, how about if we compute from random notes on up?

Program Example #35

Example Java Code: **10 random notes SongPhrase**

```
/*
   * 10 random notes
   **/
  static public Phrase random() {
    Phrase ranPhrase = new Phrase();
    Note n = null;
```

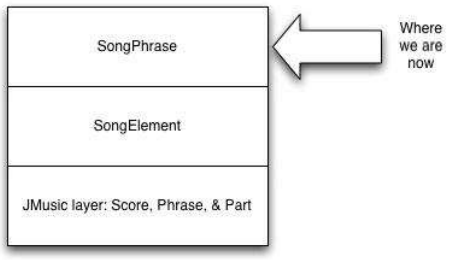

Figure 6.13: We now have layers of software, where we deal with only one at a time

```
    for (int i=0; i < 10; i++) {
      n = new Note((int) (128*Math.random()),0.1);
      ranPhrase.addNote(n);
    }
    return ranPhrase;
  }
```

How it works: Math.random() returns a number between 0.0 and 1.0. There are 128 possible notes in MIDI. Multiplying 128*Math.random() gives us a note between 0 and 127. These are 10 completely random notes.

Complete randomness isn't the most pleasant thing to listen to. We can control the randomness a bit, mathematically.

Example Java Code: **10 slightly less random notes**

Program Example #36

```
/*
   * 10 random notes above middle C
   **/
  static public Phrase randomAboveC() {
    Phrase ranPhrase = new Phrase();
    Note n = null;

    for (int i=0; i < 10; i++) {
      n = new Note((int) (60+(5*Math.random())),0.25);
      ranPhrase.addNote(n);
    }
    return ranPhrase;
  }
```

How it works: Here, we generate a random number between 0 and 4 by multiplying Math.random() by 5. Recall that note 60 is middle C. If we add our random number to 60, we play one of the five notes just above middle C.

We obviously can keep going from there. Perhaps we might generate a random number, then use it to choose (as if flipping a coin) between some different phrases to combine. Or perhaps we use arithmetic to only choose among certain notes (not necessarily in a range—perhaps selected from an array) that we want in our composition. It is really possible to have a computer "compose" music driven by random numbers.

6.7 Exploring Music

What we've built for music exploration is *okay*, but not great. What's wrong with it?

- It's hard to use. We have to specify each phrase's start time and instrument. That's a lot of specification, and it doesn't correspond to how musicians tend to think about music structure. More typically, musicians see a single music *part* as having a single instrument and start time (much as the structure of the class Part in the underlying JMusic classes).
- While we have a linked list for connecting the elements of our songs, we don't *use* the linked list for anything. Because each element has its own start time, there is no particular value to having an element before or after any other song element.

The way we're going to address these problems is by a *refactoring*. We are going to *move* a particular aspect of our design to another place in our design. Currently, every instance of SongElement has its own Part instance–that's why we specify the instrument and start time when we create the SongElement. What if we move the creation of the part until we collect all the SongElement phrases? Then we don't have to specify the instrument and start time until later. What's more, the ordering of the linked list will define the ordering of the note phrases.

Computer Science Idea: Refactoring refines a design.

We refactor designs in order to improve them. Our early decisions about where to what aspect of a piece of software might prove to be inflexible or downright *wrong* (in the sense of not describing what we want to describe) as we continue to work. Refactoring is a process of simplifying and improving a design.

* * *

There is a cost to this design. There will be only *one* instrument and start time associated with a list of song elements. We'll correct that problem in the next section.

We're going to rewrite our SongElement class for this new design, and we're going to give it a fairly geeky, abstract name–in order to make a point. We're going to name our class SongNode to highlight that each element in the song is now a *node* in a *list* of song elements. Computer scientists typically use the term node to describe pieces in a list or *tree*.

Example Java Code: **SongNode class**

Program Example #37

```
import jm.music.data.*;
import jm.JMC;
import jm.util.*;
import jm.music.tools.*;

public class SongNode {
  /**
   * the next SongNode in the list
   */
  private SongNode next;
  /**
   * the Phrase containing the notes and durations associated with this node
   */
  private Phrase myPhrase;

  /*
   * When we make a new element, the next part is empty, and ours is a blank new part
   */
  public SongNode(){
    this.next = null;
    this.myPhrase = new Phrase();
  }

  /*
   * setPhrase takes a Phrase and makes it the one for this node
   * @param thisPhrase the phrase for this node
   */
  public void setPhrase(Phrase thisPhrase){
     this.myPhrase = thisPhrase;
  }

  /*
```

```
34      * Creates a link between the current node and the input node
        * @param nextOne the node to link to
36      */
    public void setNext(SongNode nextOne){
38      this.next = nextOne;
    }
40
    /*
42      * Provides public access to the next node.
        * @return a SongNode instance (or null)
44      */
    public SongNode next(){
46      return this.next;
    }
48
    /*
50      * Accessor for the node's Phrase
        * @return internal phrase
52      */
    private Phrase getPhrase(){
54      return this.myPhrase;
    }
56
    /*
58      * Accessor for the notes inside the node's phrase
        * @return array of notes and durations inside the phrase
60      */
    private Note [] getNotes(){
62      return this.myPhrase.getNoteArray();
    }
64
    /*
66      * Collect all the notes from this node on
        * in an part (then a score) and open it up for viewing.
68      * @param instrument MIDI instrument (program) to be used in playing this list
        */
70  public void showFromMeOn(int instrument){
      // Make the Score that we'll assemble the elements into
72    // We'll set it up with a default time signature and tempo we like
      // (Should probably make it possible to change these -- maybe with inputs?)
74      Score myScore = new Score("My Song");
        myScore.setTimeSignature(3,4);
76      myScore.setTempo(120.0);

78      // Make the Part that we'll assemble things into
        Part myPart = new Part(instrument);
80
        // Make a new Phrase that will contain the notes from all the phrases
82      Phrase collector = new Phrase();
```

```
84        // Start from this element (this)
          SongNode current = this;
86        // While we're not through...
          while (current != null)
88        {
            collector.addNoteList(current.getNotes());
90
            // Now, move on to the next element
92          current = current.next();
          };
94
          // Now, construct the part and the score.
96        myPart.addPhrase(collector);
          myScore.addPart(myPart);
98
          // At the end, let's see it!
100       View.notate(myScore);

102     }

104   }
```

We can use this new class to do some of the things that we did before (Figure 6.14).

```
> SongNode first = new SongNode();
> first.setPhrase(SongPhrase.riff1());
> import jm.JMC; // We'll need this!
> first.showFromMeOn(JMC.FLUTE); // We can play with just one node
-- Constructing MIDI file from'My Song'... Playing with JavaSound
... Completed MIDI playback --------
> SongNode second = new SongNode();
> second.setPhrase(SongPhrase.riff2());
> first.next(second);  // OOPS!
Error: No 'next' method in 'SongNode' with arguments: (SongNode)
> first.setNext(second);
> first.showFromMeOn(JMC.PIANO);
```

Remember the documentation for the JMusic classes that we saw earlier in the book? That documentation can actually be automatically generated from the comments that we provide. *Javadoc* is the name for the specialized commenting structure and the tool that generates HTML documentation from that structure. The commenting structure is: (XXX-TODO See DrJava docs for now.) (Figure 6.15

Now Let's Play!

Now we can really play with repetition and weaving in at regular intervals– stuff of real music! Let's create two new methods: One that repeats an in-

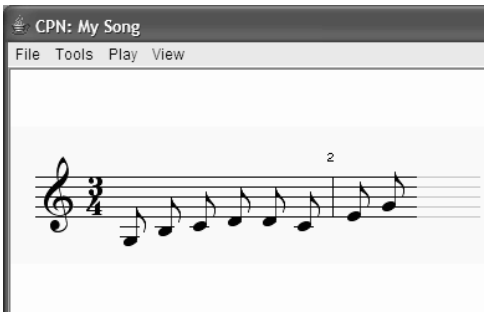

Figure 6.14: First score generated from ordered linked list

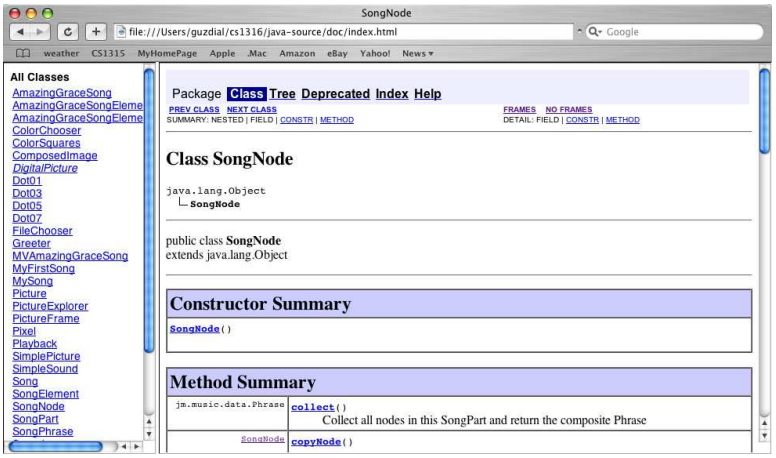

Figure 6.15: Javadoc for the class SongNode

put phrase several times, and one that weaves in a phrase every n nodes.

Program Example #38

Example Java Code: **Repeating and weaving methods**

```
/*
 * copyNode returns a copy of this node
 * @return another song node with the same notes
 */
public SongNode copyNode(){
  SongNode returnMe = new SongNode();
  returnMe.setPhrase(this.getPhrase());
  return returnMe;
```

```
    }

    /**
     * Repeat the input phrase for the number of times specified.
     * It always appends to the current node, NOT insert.
     * @param nextOne node to be copied in to list
     * @param count number of times to copy it in.
     */
    public void repeatNext(SongNode nextOne,int count) {
      SongNode current = this; // Start from here
      SongNode copy; // Where we keep the current copy

      for (int i=1; i <= count; i++)
      {
        copy = nextOne.copyNode(); // Make a copy
        current.setNext(copy); // Set as next
        current = copy; // Now append to copy
      }
    }

    /**
     * Insert the input SongNode AFTER this node,
     * and make whatever node comes NEXT become the next of the input node.
     * @param nextOne SongNode to insert after this one
     */
    public void insertAfter(SongNode nextOne)
    {
        SongNode oldNext = this.next(); // Save its next
        this.setNext(nextOne); // Insert the copy
        nextOne.setNext(oldNext); // Make the copy point on to the rest

    }

    /**
     * Weave the input phrase count times every skipAmount nodes
     * @param nextOne node to be copied into the list
     * @param count how many times to copy
     * @param skipAmount how many nodes to skip per weave
     */
    public void weave(SongNode nextOne, int count, int skipAmount)
    {
      SongNode current = this; // Start from here
      SongNode copy; // Where we keep the one to be weaved in
      SongNode oldNext; // Need this to insert properly
      int skipped; // Number skipped currently

      for (int i=1; i <= count; i++)
      {
        copy = nextOne.copyNode(); // Make a copy

```

```
        //Skip skipAmount nodes
60      skipped = 1;
        while ((current.next() != null) && (skipped < skipAmount))
62      {
          current = current.next();
64        skipped++;
        };
66
        if (current.next() == null) // Did we actually get to the end early?
68        break; // Leave the loop

70      oldNext = current.next(); // Save its next
        current.insertAfter(copy); // Insert the copy after this one
72      current = oldNext; // Continue on with the rest
      }
74  }
```

First, let's make 15 copies of one pattern (Figure 6.16).

```
> import jm.JMC;
> SongNode first = new SongNode();
> SongNode riff1 = new SongNode();
> riff1.setPhrase(SongPhrase.riff1());
> first.repeatNext(riff1,15);
> first.showFromMeOn(JMC.FLUTE);
```

Figure 6.16: Repeating a node several times

Now, let's weave in a second pattern every-other (off by 1) node, for seven times (Figure 6.17).

```
> SongNode riff2 = new SongNode();
> riff2.setPhrase(SongPhrase.riff2());
> first.weave(riff2,7,1);
> first.showFromMeOn(JMC.PIANO);
```

And we can keep weaving in more.

```
> SongNode another = new SongNode();
> another.setPhrase(SongPhrase.rhythm1());
> first.weave(another,10,2);
> first.showFromMeOn(JMC.STEEL_DRUMS);
```

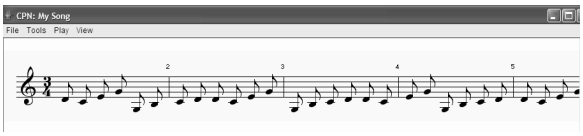

Figure 6.17: Weaving a new node among the old

Now, repeatNext is not the most polite method in the world. Consider what happens if we call it on node1 and node1 *already has a next!*. The rest of the list simply gets blown away! But now that we have insertAfter, we can produce a more friendly and polite version, repeatNextInserting, which preserves the rest of the list.

Example Java Code: **RepeatNextInserting**

Program Example #39

```
/**
  * Repeat the input phrase for the number of times specified.
  * But do an insertion, to save the rest of the list.
  * @param nextOne node to be copied into the list
  * @param count number of times to copy it in.
  **/
 public void repeatNextInserting(SongNode nextOne, int count){
   SongNode current = this; // Start from here
   SongNode copy; // Where we keep the current copy

   for (int i=1; i <= count; i++)
   {
     copy = nextOne.copyNode(); // Make a copy
     current.insertAfter(copy); // INSERT after current
     current = copy; // Now append to copy
   }
 }
```

Linked Lists versus Arrays

What are the advantages of using linked lists here, rather than arrays? They are *not* all in the favor of linked lists!

How complicated is it to traverse a linked list (visit all the elements) versus an array? Here's a linked list traversal:

```
//TRAVERSING A LIST
    // Start from this element (this)
     AmazingGraceSongElement2 current = this;
```

```
      // While we're not through...
      while (current != null)
      {
        // Set the channel, increment the channel, then add it in.
//BLAH BLAH BLAH (Ignore this part for now)

        // Now, move on to the next element
     current = current.next();
      };
```

Basically, we're walking hand-over-hand across all the nodes in the list. Think of current as your right hand.

- We put our right hand (current) on the node at **this**.
- Is our right hand empty? **while** (current= null)!?
- Process our right hand.
- Then with your left hand feel down the next link to the next node—that's what current.next() is doing.
- Now, grab with your right hand whatever your left hand was holding—current = current.next().
- Back to the top of the loop to see if our right hand is empty.
- When we reach the end of the list, our right hand is holding nothing.

Traversing an array is much easier: it's just a **for** loop.

```
> // Now, traverse the array and gather them up.
> Phrase myphrase = new Phrase()
> for (int i=0; i<100; i++)
  {myphrase.addNote( someNotes[i]);}
```

But what if we want to change something in the middle? That's where linked lists shine. Here's inserting something into the middle of a linked list:

```
> part1.setNext(part3);
> part3.setNext(part2);
> part1.showFromMeOn();
```

You know that those setNext calls are just a single line of code.

How about inserting into the middle of an array? We saw that in the last chapter and below. This code is not only long and complicated, but it is also slow. Insertion into a linked list is $O(1)$—it always takes the same amount of time, no matter how big the things are being inserted. Insertion into the middle of an array (presuming that you move things over to make room, like the insertion in the linked list does) is $O(n)$. That will always be slower.

```
public void insertAfter(Sound inSound, int start){

    SoundSample current=null;
    // Find how long insound is
    int amtToCopy = inSound.getLength();
    int endOfThis = this.getLength()-1;
    // If too long, copy only as much as will fit
    if (start + amtToCopy > endOfThis)
    {amtToCopy = endOfThis-start-1;};

    // ** First, clear out room.
    // Copy from endOfThis-amtToCopy up to endOfThis
    for (int i=endOfThis-amtToCopy; i > start ; i--)
    {
      current = this.getSample(i);
      current.setValue(this.getSampleValueAt(i+amtToCopy));
    }

    //** Second, copy in inSound up to amtToCopy
    for (int target=start,source=0;
         source < amtToCopy;
         target++, source++) {
      current = this.getSample(target);
      current.setValue(inSound.getSampleValueAt(source));
    }
  }
```

Which one is more memory efficient, that is, stores the same information in less memory? Arrays are more efficient, certainly. For every element in the linked list, there is additional memory needed to keep track of "And here's the next one." It is really quite clear which note follows which other note in an array.

On the other hand, if you do not know the size of the thing that you want before you get started—if maybe you will have dozens of notes one time, and hundreds the next—then linked lists have a distinct advantage. Arrays cannot grow, nor shrink. They simply are the size that they are. Typically, then, you make your arrays larger than you think that you will need—which is a memory inefficiency of its own. Linked lists can grow or shrink as needed.

Creating a Music Tree

Now, let's get back to the problem of having multiple parts, something we lost when we went to the ordered linked list implementation. We'll create a SongPart class that will store the instrument and the start of a SongPhrase list. Then we'll create a Song class that will store multiple parts–two parts, each a list of nodes. This structure is a start toward a *tree* structure.

* * *

Program Example #40 Example Java Code: **SongPart class**

```
import jm.music.data.*; import jm.JMC; import jm.util.*; import
jm.music.tools.*;

public class SongPart {

  /*
   * SongPart has a Part
   */
  public Part myPart;
  /*
   * SongPart has a SongNode that is the beginng of its
   */
  public SongNode myList;

  /**
   * Construct a SongPart
   * @param instrument MIDI instrument (program)
   * @param startNode where the song list starts from
   */
  public SongPart(int instrument, SongNode startNode)
  {
    myPart = new Part(instrument);
    myList = startNode;
  }

  /**
   * Collect parts of this SongPart
   */
  public Phrase collect(){
    return this.myList.collect();  // delegate to SongNode's collect
  }

   /**
   * Collect all notes in this SongPart and open it up for viewing.
   */
  public void show(){
    // Make the Score that we'll assemble the part into
    // We'll set it up with a default time signature and tempo we like
    // (Should probably make it possible to change these -- maybe with inputs?)
     Score myScore = new Score("My Song");
     myScore.setTimeSignature(3,4);
     myScore.setTempo(120.0);

     // Now, construct the part and the score.
```

```
        this.myPart.addPhrase(this.collect());
46      myScore.addPart(this.myPart);

48      // At the end, let's see it!
        View.notate(myScore);
50
    }
52
}
```

Example Java Code: **Song class–root of a tree-like music structure** *Program Example #41*

```
import jm.music.data.*; import jm.JMC; import jm.util.*; import
2 jm.music.tools.*;

4 public class Song {
    /**
6    * first Channel
     */
8   public SongPart first;

10  /**
     * second Channel
12   */
    public SongPart second;
14
    /**
16   * Take in a SongPart to make the first channel in the song
     */
18  public void setFirst(SongPart channel1){
      first = channel1;
20    first.myPart.setChannel(1);
    }
22
    /**
24   * Take in a SongPart to make the second channel in the song
     */
26  public void setSecond(SongPart channel2){
      second = channel2;
28    first.myPart.setChannel(2);
    }
30
    public void show(){
32    // Make the Score that we'll assemble the parts into
      // We'll set it up with a default time signature and tempo we like
```

```
34      // (Should probably make it possible to change these — maybe with inputs?)
        Score myScore = new Score("My Song");
36      myScore.setTimeSignature(3,4);
        myScore.setTempo(120.0);
38
        // Now, construct the part and the score.
40      first.myPart.addPhrase(first.collect());
        second.myPart.addPhrase(second.collect());
42      myScore.addPart(first.myPart);
        myScore.addPart(second.myPart);
44
        // At the end, let's see it!
46      View.notate(myScore);

48    }

50
  }
```

While our new structure is very flexible, it's not the easiest thing to use. We don't want to have to type everything into the Interactions Pane every time. So, we'll create a class that has its main method that will run on its own. You can execute it using RUN DOCUMENT'S MAIN METHOD (F2) in the TOOLS menu. Using MySong, we can get back to having multi-part music in a single score (Figure 6.18).

Program Example #42

Example Java Code: **MySong class with a main metho0d**

```
  import jm.music.data.*;
2 import jm.JMC;
  import jm.util.*;
4 import jm.JMC;

6 public class MyFirstSong {
    public static void main(String [] args) {
8     Song songroot = new Song();

10    SongNode node1 = new SongNode();
      SongNode riff3 = new SongNode();
12    riff3.setPhrase(SongPhrase.riff3());
      node1.repeatNext(riff3,16);
14    SongNode riff1 = new SongNode();
      riff1.setPhrase(SongPhrase.riff1());
16    node1.weave(riff1,7,1);
      SongPart part1 = new SongPart(JMC.PIANO, node1);
```

```
18
        songroot.setFirst(part1);
20
        SongNode node2 = new SongNode();
22      SongNode riff4 = new SongNode();
        riff4.setPhrase(SongPhrase.riff4());
24      node2.repeatNext(riff4,20);
        node2.weave(riff1,4,5);
26      SongPart part2 = new SongPart(JMC.STEEL_DRUMS, node2);

28      songroot.setSecond(part2);
        songroot.show();
30    }
  }
```

Figure 6.18: Multi-part song using our classes

The point of all of this is to create a *structure* which enables us easily to explore music compositions, in the ways that we will most probably want to explore. We imagine that most music composition exploration will consist of defining new phrases of notes, then combining them in interesting ways: defining which come after which, repeating them, and weaving them in with the rest. At a later point, we can play with which instruments we want to use to play our parts.

Exercises

1. The Song structure that we've developed on *top* of JMusic is actually pretty similar to the actual implementation of the classes Score, Part, and Phrase *within* the JMusic system. Take one of the music examples that we've built with our own linked list, and re-implement it using only the JMusic classes.

2. Add into Song the ability to record different starting times for the composite SongParts. It's the internal Phrase that remembers the start time, so you'll have to pass it down the structure.

3. The current implementation of repeatAfter in SongNode append's the input node, as opposed to inserting it. If you could insert it, then you could repeat a bunch of a given phrase *between* two other nodes. Create a repeatedInsert method that does an insertion rather than an append.

4. The current implementation of Song implements *two* channels. Channel *nine* is the *MIDI Drum Kit* where the notes are different percussion instruments (Figure 6.2). Modify the Song class take a third channel, which gets assigned to MIDI channel 9 and plays a percussion SongPart.

35	Acoustic Bass Drum	51	Ride Cymbal 1
36	Bass Drum 1	52	Chinese Cymbal
37	Side Stick	53	Ride Bell
38	Acoustic Snare	54	Tambourine
39	Hand Clap	55	Splash Cymbal
40	Electric Snare	56	Cowbell
41	Lo Floor Tom	57	Crash Cymbal 2
42	Closed Hi Hat	58	Vibraslap
43	Hi Floor Tom	59	Ride Cymbal 2
44	Pedal Hi Hat	60	Hi Bongo
45	Lo Tom Tom	61	Low Bongo
46	Open Hi Hat	62	Mute Hi Conga
47	Low -Mid Tom Tom	63	Open Hi Conga
48	Hi Mid Tom Tom	64	Low Conga
49	Crash Cymbal 1	65	Hi Timbale
50	Hi Tom Tom	66	Lo Timbale

Table 6.2: MIDI Drum Kit Notes

5. Using the methods developed in class to play with linked list of music, create a song.

   - You must use weave and repeatNext (or repeatNextInserting) to create patterns in your music. You probably want to use the SongNode and SongPhrase classes.
   - You must use weave and either of the repeats *at least **five*** in your piece. In other words, repeat a set of nodes, then repeat another set, then repeat another set. Then weave in nodes with one pattern, then weave in nodes with another pattern. That would be five. Or do one repeat to create a basic tempo, then four weaves to bring in other motifs.
   - You must use at least four unique riffs from SongPhrase. (It's okay for you to make all four of them yourself.)

- You must also create your own riffs in SongPhrase. You can simply type in music, or you can compute your riff any way you want to do it is fine. Just create at least one phrase (of more than a couple notes) that is interesting and unique.
- All told, you must have at least 10 nodes in your final song.

You will create a class (with some cunning name like MyWovenSong) with a main that will assemble your song, then open it with showFromMeOn (or showwhatever you need to do open up the notation View on your masterpiece).

Here's the critical part: Draw a picture of your resultant list structure. Show us where all the nodes are in your final composition. You can do this by drawing with a tool like Paint or Visio or even PowerPoint, or you can draw it on paper then scan it in. You can turn in JPEG, TIFF, or PPT files.

7 Structuring Images using Linked Lists

Chapter Learning Objectives

The villagers and wildebeests scenes are not single images. They are collections of many images–not just of the villagers and wildebeests themselves, but of the elements of the scene, too. How do we structure these images? We could use arrays, but that doesn't give us enough flexibility to insert new pictures, make things disappear (delete them from the scene), and move elements around. To do that, we will need *linked lists* of images.
The computer science goals for this chapter are:

- To use and manipulate linked lists (of images).
- To use an *abstract superclass* to create a single linked list of multiple kinds of objects.

The media learning goals for this chapter are:

- To use different interpretations of the linearity of linked lists: to represent left-to-right ordering, or to represent front-to-back ordering (or *layering*).

We know a lot about manipulating individual images. We know how to manipulate the pixels of an image to create various effects. We've encapsulated a bunch of these in methods to make them pretty easy to use. The question is how to build up these images into composite images. How do we create *scenes* made up of lots of images?

When computer graphics and animation professionals construct complicated scenes such as in *Toy Story* and *Monsters, Inc.*, they go beyond thinking about individual images. Certainly, at some point, they care about how Woody and Nemo are created, how they look, and how they get inserted into the frame–but all as part of how the *scene* is constructed.

How do we describe the structure of a scene? How do we structure our objects in order to describe scenes that we want to describe, but what's more, how do we describe them in such a way that we can change the scene (e.g., in order to define an animation) in the ways that we'll want to later? Those are the questions of this chapter.

7.1 Simple arrays of pictures

The simplest thing to do is to simply list all the pictures we want in array. We then compose them each into a background (Figure 7.1).

```
> Picture [] myarray = new Picture[5];
> myarray[0]=new Picture(FileChooser.getMediaPath("katie.jpg"));
> myarray[1]=new Picture(FileChooser.getMediaPath("barbara.jpg"));
> myarray[2]=new Picture(FileChooser.getMediaPath("flower1.jpg"));
> myarray[3]=new Picture(FileChooser.getMediaPath("flower2.jpg"));
> myarray[4]=new Picture(FileChooser.getMediaPath("butterfly.jpg"));
> Picture background = new Picture(400,400)
> for (int i = 0; i < 5; i++)
   {myarray[i].scale(0.5).compose(background,i*10,i*10);}
> background.show();
```

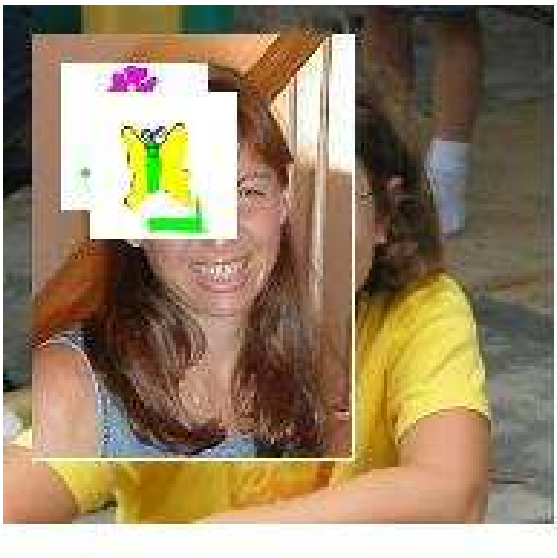

Figure 7.1: Array of pictures composed into a background

7.2 Listing the Pictures, Left-to-Right

We met a *linked list* in the last chapter. We can use the same concept for images.

Let's start out by thinking about a scene as a collection of pictures that lay next to one another. Each element of the scene is a picture and knows the next element in the sequence. The elements form a *list* that is *linked* together–that's a *linked list*.

We'll use three little images drawn on a blue background, to make them easier to chromakey into the image (Figure 7.2).

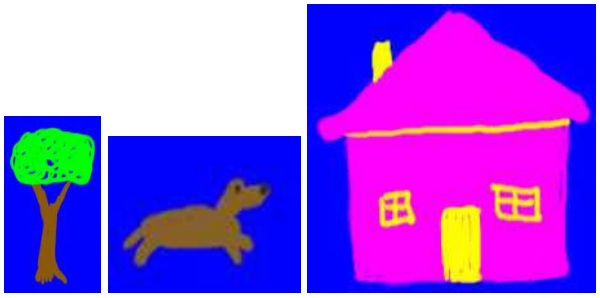

Figure 7.2: Elements to be used in our scenes

Example Java Code: **Elements of a scene in position order**

Program Example #43

```
public class PositionedSceneElement {

  /**
   * the picture that this element holds
   **/
  private Picture myPic;

  /**
   * the next element in the list
   **/
  private PositionedSceneElement next;

  /**
   * Make a new element with a picture as input, and
   * next as null.
   * @param heldPic Picture for element to hold
   **/
  public PositionedSceneElement(Picture heldPic){
    myPic = heldPic;
    next = null;
  }

  /**
   * Methods to set and get next elements
   * @param nextOne next element in list
   **/
  public void setNext(PositionedSceneElement nextOne){
```

```
28      this.next = nextOne;
    }
30
    public PositionedSceneElement getNext(){
32      return this.next;
    }
34
    /**
36   * Returns the picture in the node.
     * @return the picture in the node
38   **/
    public Picture getPicture(){
40      return this.myPic;
    }
42
    /**
44   * Method to draw from this node on in the list, using bluescreen.
     * Each new element has it's lower-left corner at the lower-right
46   * of the previous node. Starts drawing from left-bottom
     * @param bg Picture to draw drawing on
48   **/
    public void drawFromMeOn(Picture bg) {
50      PositionedSceneElement current;
        int currentX=0, currentY = bg.getHeight()-1;
52
        current = this;
54      while (current != null)
        {
56        current.drawMeOn(bg,currentX, currentY);
          currentX = currentX + current.getPicture().getWidth();
58        current = current.getNext();
        }
60  }

62  /**
     * Method to draw from this picture, using bluescreen.
64   * @param bg Picture to draw drawing on
     * @param left x position to draw from
66   * @param bottom y position to draw from
     **/
68
    private void drawMeOn(Picture bg, int left, int bottom) {
70      // Bluescreen takes an upper left corner
        this.getPicture().bluescreen(bg,left,
72                                   bottom-this.getPicture().getHeight());
    }
74  }
```

* * *

To construct a scene, we create our PositionedSceneElement objects from the original three pictures. We connect the elements in order, then draw them all onto a background (Figure 7.3).

```
> PositionedSceneElement tree1 =
  new PositionedSceneElement(new Picture(FileChooser.getMediaPath("tree-blue.jpg")));
> PositionedSceneElement tree2 =
  new PositionedSceneElement(new Picture(FileChooser.getMediaPath("tree-blue.jpg")));
> PositionedSceneElement tree3 =
  new PositionedSceneElement(new Picture(FileChooser.getMediaPath("tree-blue.jpg")));
> PositionedSceneElement doggy =
  new PositionedSceneElement(new Picture(FileChooser.getMediaPath("dog-blue.jpg")));
> PositionedSceneElement house =
  new PositionedSceneElement(new Picture(FileChooser.getMediaPath("house-blue.jpg")));
> Picture bg = new Picture(FileChooser.getMediaPath("jungle.jpg"));
> tree1.setNext(tree2); tree2.setNext(tree3); tree3.setNext(doggy); doggy.setNext(house);
> tree1.drawFromMeOn(bg);
> bg.show();
> bg.write("D:/cs1316/first-house-scene.jpg");
```

Figure 7.3: Our first scene

This successfully draws a scene, but is it easy to recompose into new scenes? Let's say that we decide that we actually want the dog between trees two and three, instead of tree three and the house. To change the list, we need tree2 to point at the doggy element, doggy to point at tree3, and tree3 to point at the house (what the doggy used to point at). Then redraw the scene on a new background (Figure 7.4).

```
> tree3.setNext(house); tree2.setNext(doggy); doggy.setNext(tree3);
> bg = new Picture(FileChooser.getMediaPath("jungle.jpg"));
> tree1.drawFromMeOn(bg);
```

```
> bg.show();
> bg.write("D:/cs1316/second-house-scene.jpg");
```

Figure 7.4: Our second scene

Generalizing moving the element

Let's consider what happened in this line:

```
> tree3.setNext(house); tree2.setNext(doggy); doggy.setNext(tree3);
```

The first statement, tree3.setNext(house);, gets the doggy out of the list. tree3 used to point to (setNext) doggy. The next two statements put the doggy after tree2. The second statement, tree2.setNext(doggy);, puts the doggy after tree2. The last statement, doggy.setNext(tree3);, makes the doggy point at what tree2 *used* to point at. All together, the three statements in that line:

- Remove the item doggy from the list.
- Insert the item doggy after tree2.

We can write methods to allow us to do this removing and insertion more generally.

Program Example #44

Example Java Code: **Methods to remove and insert elements in a list**

```
/** Method to remove node from list, fixing links appropriately.
 * @param node element to remove from list.
 **/
```

```
4   public void remove(PositionedSceneElement node){
      if (node==this)
6     {
        System.out.println("I can't remove the first node from the list.");
8       return;
      };
10
      PositionedSceneElement current = this;
12    // While there are more nodes to consider
      while (current.getNext() != null)
14    {
        if (current.getNext() == node){
16        // Simply make node's next be this next
          current.setNext(node.getNext());
18        // Make this node point to nothing
          node.setNext(null);
20        return;
        }
22      current = current.getNext();
      }
24  }

26  /**
     * Insert the input node after this node.
28   * @param node element to insert after this.
     **/
30  public void insertAfter(PositionedSceneElement node){
      // Save what "this" currently points at
32    PositionedSceneElement oldNext = this.getNext();
      this.setNext(node);
34    node.setNext(oldNext);
    }
```

The first method allows us to remove an element from a list, like this:

```
> tree1.setNext(tree2); tree2.setNext(tree3); tree3.setNext(doggy); doggy.setNext(house);
> tree1.remove(doggy);
> tree1.drawFromMeOn(bg);
```

The result is that doggy is removed entirely (Figure 7.5).

Now we can re-insert the doggy wherever we want, say, after tree1 (Figure 7.6):

```
> bg = new Picture(FileChooser.getMediaPath("jungle.jpg"));
> tree1.insertAfter(doggy);
> tree1.drawFromMeOn(bg);
```

Figure 7.5: Removing the doggy from the scene

Figure 7.6: Inserting the doggy into the scene

7.3 Listing the Pictures, Layering

In the example from last section, we used the *order* of the elements in the linked list to determine *position*. We can decide what our representations encode. Let's say that we didn't want to just have our elements be in a linear sequence–we wanted them to each know their positions anywhere on the screen. What, then, would order in the linked list encode? As we'll see, it will encode *layering*.

* * *

Example Java Code: **LayeredSceneElements**

Program Example #45

```
public class LayeredSceneElement {

  /**
   * the picture that this element holds
   **/
  private Picture myPic;

  /**
   * the next element in the list
   **/
  private LayeredSceneElement next;

  /**
   * The coordinates for this element
   **/
  private int x, y;

  /**
   * Make a new element with a picture as input, and
   * next as null, to be drawn at given x,y
   * @param heldPic Picture for element to hold
   * @param xpos x position desired for element
   * @param ypos y position desired for element
   **/
  public LayeredSceneElement(Picture heldPic, int xpos, int ypos){
    myPic = heldPic;
    next = null;
    x = xpos;
    y = ypos;
  }

  /**
   * Methods to set and get next elements
   * @param nextOne next element in list
   **/
  public void setNext(LayeredSceneElement nextOne){
    this.next = nextOne;
  }

  public LayeredSceneElement getNext(){
    return this.next;
  }

  /**
   * Returns the picture in the node.
```

```
46      * @return the picture in the node
        **/
48    public Picture getPicture(){
        return this.myPic;
50    }

52    /**
       * Method to draw from this node on in the list, using bluescreen.
54     * Each new element has it's lower-left corner at the lower-right
       * of the previous node. Starts drawing from left-bottom
56     * @param bg Picture to draw drawing on
       **/
58    public void drawFromMeOn(Picture bg) {
        LayeredSceneElement current;
60
        current = this;
62      while (current != null)
        {
64        current.drawMeOn(bg);
          current = current.getNext();
66      }
      }
68
      /**
70     * Method to draw from this picture, using bluescreen.
       * @param bg Picture to draw drawing on
72     **/

74    private void drawMeOn(Picture bg) {
         this.getPicture().bluescreen(bg,x,y);
76    }

78    /** Method to remove node from list, fixing links appropriately.
       * @param node element to remove from list.
80     **/
      public void remove(LayeredSceneElement node){
82      if (node==this)
        {
84        System.out.println("I can't remove the first node from the list.");
          return;
86      };

88      LayeredSceneElement current = this;
        // While there are more nodes to consider
90      while (current.getNext() != null)
        {
92        if (current.getNext() == node){
            // Simply make node's next be this next
94          current.setNext(node.getNext());
            // Make this node point to nothing
```

```
96            node.setNext(null);
              return;
98          }
            current = current.getNext();
100       }
      }
102
      /**
104    * Insert the input node after this node.
       * @param node element to insert after this.
106    **/
      public void insertAfter(LayeredSceneElement node){
108     // Save what "this" currently points at
        LayeredSceneElement oldNext = this.getNext();
110     this.setNext(node);
        node.setNext(oldNext);
112   }
}
```

Our use of LayeredSceneElement is much the same as the PositionedSceneElement, except that when we create a new element, we also specify its position on the screen.

```
> Picture bg = new Picture(400,400);
> LayeredSceneElement tree1 = new LayeredSceneElement(
new Picture(FileChooser.getMediaPath("tree-blue.jpg")),10,10);
> LayeredSceneElement tree2 = new LayeredSceneElement(
new Picture(FileChooser.getMediaPath("tree-blue.jpg")),100,10);
> LayeredSceneElement tree3 = new LayeredSceneElement(
new Picture(FileChooser.getMediaPath("tree-blue.jpg")),200,100);
> LayeredSceneElement house = new LayeredSceneElement(
new Picture(FileChooser.getMediaPath("house-blue.jpg")),175,175);
> LayeredSceneElement doggy = new LayeredSceneElement(
new Picture(FileChooser.getMediaPath("dog-blue.jpg")),150,325);
> tree1.setNext(tree2); tree2.setNext(tree3); tree3.setNext(doggy); doggy.setNext(house);
> tree1.drawFromMeOn(bg);
> bg.show();
> bg.write("D:/cs1316/first-layered-scene.jpg");
```

The result (Figure 7.7) shows the house in front of a tree and the dog. In the upper left, we can see one tree overlapping the other.

How it works: Let's talk about how one piece of this class works, the removal of a node.

```
  /** Method to remove node from list, fixing links appropriately.
   * @param node element to remove from list.
   **/
  public void remove(LayeredSceneElement node){
```

Figure 7.7: First rendering of the layered sene

```
    if (node==this)
    {
      System.out.println("I can't remove the first node from the list.");
      return;
    };

    LayeredSceneElement current = this;
    // While there are more nodes to consider
    while (current.getNext() != null)
    {
      if (current.getNext() == node){
        // Simply make node's next be this next
        current.setNext(node.getNext());
        // Make this node point to nothing
        node.setNext(null);
        return;
      }
      current = current.getNext();
    }
  }
```

You might be wondering what that @param is about in the comments. This is a note to JavaDoc that the method remove takes a parameter. What comes after @param is a the parameter name, and then a comment explaining the parameter. This comment will appear in the JavaDoc to explain

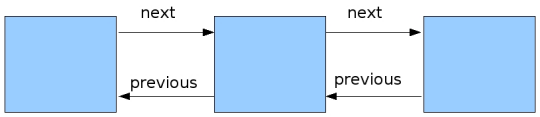

Figure 7.8: A doubly-linked list

what the method does and how to use it.

The first thing we do in remove is to check to see if the node to be removed is the same node that we asked to do the remove, **this**. Typically, you call remove on the first node in the list. Currently, our implemention of lists doesn't allow us to remove the first node in the list. If we execute hisOnethisOne.removet, how could we change thisOne to point at anything else? We'll see how to fix that later.

We then traverse the list, checking for current.getNext()= null!. That's a little unusual—typically, we're checking for current= null! when we traverse a list. Why the difference? Because we want to find the node *before* the one we're removing. We need to connect the nodes *around* the node that that's already there. Once we find the node to remove, we want to make the one *before* it point to whatever the removed node *currently* points to. That essentially routes the linked list around the node to be removed—and poof! it's gone. If we stopped when we found the node we were looking for, as opposed to current.getNext() being the node we are looking for, we will have gone too far. This is a key idea in linked lists: *there is no link from a node back to the node that is pointing to it*. If you have a pointer to a node, you don't know who points to that node.

That does not have to be true. One can have linked lists where a node points both to its next *and* to its previous (Figure 7.8). We call those doubly−linked lists. They are powerful for finding and replacing nodes, since you can traverse them forwards and backwards. They are more complicated, though—inserting and deleting involves patching up both next links and previous links. They also waste more space than a *singly-linked list*. With a singly-linked list, each piece of data in a node also has a next link associated with it. Compared to an array, a singly-linked list requires an extra reference for every data element. A doubly-linked list gives up *two* references for each data element.

Reordering elements in a list

Now, let's reorder the elements in the list, without changing the elements–not even their locations. We'll reverse the list so that we start with the house, not the first tree. (Notice that we set the tree1 element to point to **null**–if we didn't do that, we'd get an infinite loop with tree1 pointing to itself.)

The resultant figure (Figure 7.9) has completely different layering. The trees in the upper left have swapped, and the tree and dog are now in front of the house.

```
> house.setNext(doggy); doggy.setNext(tree3); tree3.setNext(tree2); tree2.setNext(tr
> tree1.setNext(null);
> bg = new Picture(400,400);
> house.drawFromMeOn(bg);
> bg.show();
> bg.write("D:/cs1316/second-layered-scene.jpg");
```

Figure 7.9: Second rendering of the layered sene

Have you ever used a drawing program like *Visio* or even *PowerPoint* where you brough an object forward, or sent it to back? What you were doing is, quite literally, exactly what we're doing when we're changing the order of elements in the list of PositionedSceneElements. In tools such as Visio or PowerPoint, each drawn object is an element in a list. To draw the screen, the program literally walks the list (*traverses* the list) and draws each object. We call the re-creation of the scene through traversing a data structure a *rendering* of the scene. If the list gets reordered (with bringing an object forward or sending it to the back), then the layering changes. "Bringing an object forward" is about moving an element one position further *back* in the list–the things at the end get drawn *last* and thus are on *top*.

One other observation: Did you notice how similar both of these elements implementations are?

7.4 Reversing a List

In the last example, we reversed the list "by hand" in a sense. We took each and every node and reset what it pointed to. What if we had a *lot* of elements, though? What if our scene had dozens of elements in it? Reversing the list would take a lot of commands. Could we write down the *process* of reversing the list, so that we can encode it?

There are actually several different ways of reversing a list. Let's do it in two different ways here. The first way we'll do it is by repeatedly getting the last element of the original list, removing it from the list, then adding it to the new reversed list. That will work, but slowly. To find the last element of the list means traversing the whole list. To add an element to the end of the list means walking to the end of the new list and setting the last element there to the new element.

Here's a method that implements that process.

Example Java Code: **Reverse a list**

Program Example #46

```
/**
 * Reverse the list starting at this,
 * and return the last element of the list.
 * The last element becomes the FIRST element
 * of the list, and THIS points to null.
 **/
  public LayeredSceneElement reverse() {
  LayeredSceneElement reversed, temp;

  // Handle the first node outside the loop
  reversed = this.last();
  this.remove(reversed);

  while (this.getNext() != null)
  {
    temp = this.last();
    this.remove(temp);
    reversed.add(temp);
  };

  // Now put the head of the old list on the end of
  // the reversed list.
  reversed.add(this);

  // At this point, reversed
```

```
26      // is the head of the list
        return reversed;
28    }
```

The core of this program is:

```
while (this.getNext() != null)
    {
      temp = this.last();
      this.remove(temp);
      reversed.add(temp);
    };
```

So how expensive is this loop?

- We go through this loop once for each element in the list.
- For each element in the list, we find the last() (which requires another complete traversal)
- And when we add(), which we know requires another last() which is another traversal.

The bottom line is, that for each node in the list, we touch every other node. We call that an $O(n^2)$ algorithm—as the data grows larger (n), the number of steps to execute (the running time) increases as a square of the data size (n^2). For a huge list of lots images (maybe wildebeests running down a ridge?), that's very expensive.

How would you do it in real life? Imagine that you have a bunch of cards laid out in a row, and you need to reverse them. How would you do it? One way to do it is to *pile* them up, and then set them back out. A pile (called a *stack* in computer science) has an interesting *property* in that the last thing placed on the pile is the first one to remove from the pile–that's called LIFO, *Last-In-First-Out*. We can use that property to reverse the list. We can define a Stack class to represent the abstract notion of a *pile*, then use it to reverse the list. We will see that in the next chapter.

7.5 Animation

Any movie (including animated scenes) consist of a series of images (typically called *frames*) played in a sequence fast enough to trick our eyes into seeing a continuous image. How would you create an animation using data structures? We can come up with a different definition than "a sequence of frames" now. We can think of an animation as "Modify the structure describing your scene, then *render* it (turn it into an image), and repeat!"

We can do that even with our simple linked lists. We will create an animation of a doggy at the beginning of a grove of trees, then running between the trees. At the end, he turns around and runs back.

* * *

Example Java Code: **Create a simple animation of a dog running** *Program Example #47*

```
public class AnimatedPositionedScene {

  /**
   * A FrameSequence for storing the frames
   **/
  FrameSequence frames;

  /**
   * We'll need to keep track
   * of the elements of the scene
   **/
  PositionedSceneElement tree1, tree2, tree3, house, doggy, doggyflip;

  // Set up the whole animation
  public void setUp(){
    frames = new FrameSequence("C:/Temp/");

    //FileChooser.setMediaPath("C:/cs1316/mediasources/");
    Picture p = null; // Use this to fill elements

    p = new Picture(FileChooser.getMediaPath("tree-blue.jpg"));
    tree1 = new PositionedSceneElement(p);

    p = new Picture(FileChooser.getMediaPath("tree-blue.jpg"));
    tree2 = new PositionedSceneElement(p);

    p = new Picture(FileChooser.getMediaPath("tree-blue.jpg"));
    tree3 = new PositionedSceneElement(p);

    p = new Picture(FileChooser.getMediaPath("house-blue.jpg"));
    house = new PositionedSceneElement(p);

    p = new Picture(FileChooser.getMediaPath("dog-blue.jpg"));
    doggy = new PositionedSceneElement(p);
    doggyflip = new PositionedSceneElement(p.flip());
  }

  // Render the whole animation
  public void make(){
    frames.show();

    // First frame
    Picture bg = new Picture(FileChooser.getMediaPath("jungle.jpg"));
    tree1.setNext(doggy); doggy.setNext(tree2); tree2.setNext(tree3);
    tree3.setNext(house);
```

```
46      tree1.drawFromMeOn(bg);
        frames.addFrame(bg);
48
        // Dog moving right
50      bg = new Picture(FileChooser.getMediaPath("jungle.jpg"));
        tree1.remove(doggy);
52      tree2.insertAfter(doggy);
        tree1.drawFromMeOn(bg);
54      frames.addFrame(bg);

56      bg = new Picture(FileChooser.getMediaPath("jungle.jpg"));
        tree1.remove(doggy);
58      tree3.insertAfter(doggy);
        tree1.drawFromMeOn(bg);
60      frames.addFrame(bg);

62      bg = new Picture(FileChooser.getMediaPath("jungle.jpg"));
        tree1.remove(doggy);
64      house.insertAfter(doggy);
        tree1.drawFromMeOn(bg);
66      frames.addFrame(bg);

68      //Dog moving left
        bg = new Picture(FileChooser.getMediaPath("jungle.jpg"));
70      tree1.remove(doggy);
        house.insertAfter(doggyflip);
72      tree1.drawFromMeOn(bg);
        frames.addFrame(bg);
74
        bg = new Picture(FileChooser.getMediaPath("jungle.jpg"));
76      tree1.remove(doggyflip);
        tree3.insertAfter(doggyflip);
78      tree1.drawFromMeOn(bg);
        frames.addFrame(bg);
80
        bg = new Picture(FileChooser.getMediaPath("jungle.jpg"));
82      tree1.remove(doggyflip);
        tree2.insertAfter(doggyflip);
84      tree1.drawFromMeOn(bg);
        frames.addFrame(bg);
86
        bg = new Picture(FileChooser.getMediaPath("jungle.jpg"));
88      tree1.remove(doggyflip);
        tree1.insertAfter(doggyflip);
90      tree1.drawFromMeOn(bg);
        frames.addFrame(bg);
92
    }
94
    public void replay(){
```

```
96        frames.replay(500); //3 frames per second
      }
98  }
```

This is definitely not a great animation (Figure 7.10. It looks more like the trees are hopping out of the way of the dog, like the houses hopping away from the Knight Bus in the Harry Potter novels. But this is our first example of how a real computer-generated animation works: By using a data structure, which gets changed and re-rendered in a loop.

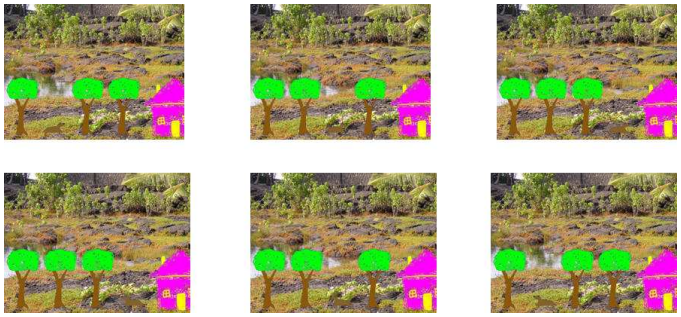

Figure 7.10: A few frames from the AnimatedPositionedScene

7.6 Lists with Two Kinds of Elements

Why should we have to choose between having elements positioned for us, left-to-right, or layered for us, back-to-front? That doesn't seem like a reasonable limitation for an animation designer — you may want some images just lined up where you don't care so much about the positioning (e.g., trees in a forest, spectators in the audience) and other images you want to be in very specific places (e.g., your main characters). We can easily imagine having a list where we have both positioned and layered elements. Some nodes we want to position left-to-right, and other nodes we'd want to go at particular places, and nodes earlier in the list would be understood to be rendered behind other nodes.

That turns out to be a new thing for us to do from a Java perspective. Consider that PositionedSceneElement. It's next has the type PositionedSceneElement. How could the next element be anything *but* a PositionedSceneElement? If the next element could be something else, we couldn't use the same how could we draw some things at their (x, y) position and *others* left-to-right?

There's another reason to rewrite our existing scene element classes, besides wanting to intermix different kinds of elements. The current implementation has *so much* duplicated code. Check out last and add in

PositionedSceneElement and LayeredSceneElement. Basically the same thing–why do we have to duplicate this code? Why can't we tell the computer "Here's last–always use this definition for all linked lists, please!"?

The way to solve both of these problems (being able to intermix kinds of elements and rewriting to reduce redundancy of code) is with a *superclass*. We will create a superclass called SceneElement, then we will create a *subclass* for positioned and layered kinds of scene elements. We'll call these SceneElementLayered and SceneElementPositioned. This structure solves several of the above problems.

- A variable that is declared the type of a superclass can *also* hold objects that have the type of a subclass. So, a variable of type SceneElement can also reference a SceneElementLayered or SceneElementPositioned. That's how we'll define next so that each element can point to any other kind of SceneElement.
- Any methods in SceneElement are *inherited* by its subclasses. So if we define last and add in SceneElement, any instances of SceneElementLayered and SceneElementPositioned will automatically inherit those methods. Every instance of SceneElementLayered and SceneElementPositioned will know how to do add and last because the superclass SceneElement knows how to do it.
- Where the subclasses need to be different, they *can* be made different. So SceneElementPositioned will have an x and y for positioned, but SceneElementLayered will not.

If one of the classes will have an (x, y) and the other one will not, each of the subclasses will have to drawWith themselves differently. The drawWith method for SceneElementPositioned will have to figure out where each element goes left-to-right, and same method for SceneElementLayered will draw the element at its desired x and y.

Since SceneElement will not actually know how to draw itself, it is not really a useful object. It is a useful class, though. A class whose main purpose is to hold methods (behavior) and fields (data and structure) that subclasses will inherit is referred to as an *abstract class*. Java even has a keyword **abstract** that is used to identify abstrat classes.

An abstract class can also have *abstract methods* (also identified with the **abstract** keyword). These are methods in an abstract class that do not actually have implementations in the abstract class—there is no body for the method. The point of defining an abstract method in an abstract class is to tell Java, "All my subclasses will define this method and provide a real body for this method. I'm just defining it here so that you know that you can expect it—it's okay for a variable declared to be *me* to call this method."

* * *

am
ple #48

Example Java Code: **Abstract method drawWith in abstract class SceneElement**

```
  /*
 * Use the given turtle to draw oneself
 * @param t the Turtle to draw with
 **/
public abstract void drawWith(Turtle t);
// No body in the superclass
```

Okay, now that we know how to declare the abstract class and the abstract method drawWith, we can consider how to implement the drawWith method for each of the subclasses of SceneElement, SceneElementPositioned and SceneElementLayered. The challenge of implementing drawWith is to keep track of the next *positioned* element when you have to go draw a *layered* element at some particular (x, y). There are lots of ways of doing that, like holding some nextX and nextY that remembers the next position even when drawing a layered element. Here's the one that we will use here: We will use a turtle to keep track of *where* the element should be drawn. Specifically, each subclass will implement drawWith taking a turtle as input, and they will use that turtle as a *pen* to draw the picture in the node at the right place.

Let's define the SceneElement abstract class first. It knows its picture and knows how to do all the basic list manipulations (Figure 7.11—yet only knows "abstractly" how to draw. A key part of this class definition is that next and all the methods that return an object are declared as class SceneElement—which means that they can actually be any instance in the hierarchy.

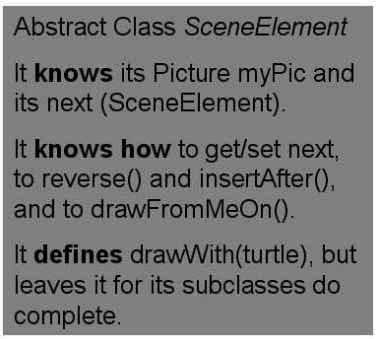

Figure 7.11: The abstract class SceneElement, in terms of what it knows and can do

Program Example #49

Example Java Code: **SceneElement**

```
/**
 * An element that knows how to draw itself in a scene with a turtle
 **/
public abstract class SceneElement{

  /**
   * the picture that this element holds
   **/
  protected Picture myPic;

  /**
   * the next element in the list -- any SceneElement
   **/
  protected SceneElement next;

  /**
   * Methods to set and get next elements
   * @param nextOne next element in list
   **/
  public void setNext(SceneElement nextOne){
    this.next = nextOne;
  }

  public SceneElement getNext(){
    return this.next;
  }

  /**
   * Returns the picture in the node.
   * @return the picture in the node
   **/
  public Picture getPicture(){
    return this.myPic;
  }

  /**
   * Method to draw from this node on in the list.
   * For positioned elements, compute locations.
   * Each new element has it's lower-left corner at the lower-right
   * of the previous node. Starts drawing from left-bottom
   * @param bg Picture to draw drawing on
   **/
  public void drawFromMeOn(Picture bg) {
```

```
    SceneElement current;
46
    // Start the X at the left
48  // Start the Y along the bottom
    int currentX=0, currentY = bg.getHeight()-1;
50
    Turtle pen = new Turtle(bg);
52  pen.setPenDown(true); // Pick the pen up

54  current = this;
    while (current != null)
56  { // Position the turtle for the next positioned element
      pen.moveTo(currentX,currentY-current.getPicture().getHeight());
58    pen.setHeading(0);

60    current.drawWith(pen);
      currentX = currentX + current.getPicture().getWidth();
62
      current = current.getNext();
64  }
  }
66
  /*
68 * Use the given turtle to draw oneself
   * @param t the Turtle to draw with
70 **/
  public abstract void drawWith(Turtle t);
72 // No body in the superclass

74 /** Method to remove node from list, fixing links appropriately.
   * @param node element to remove from list.
76 **/
  public void remove(SceneElement node){
78  if (node==this)
    {
80    System.out.println("I can't remove the first node from the list.");
      return;
82  };

84  SceneElement current = this;
    // While there are more nodes to consider
86  while (current.getNext() != null)
    {
88    if (current.getNext() == node){
        // Simply make node's next be this next
90      current.setNext(node.getNext());
        // Make this node point to nothing
92      node.setNext(null);
        return;
94    }
```

```
      current = current.getNext();
96    }
    }
98
    /**
100  * Return the count of elements in this list
     **/
102 public int count() {
      SceneElement current = this;
104   int count = 0;
      while (current != null){
106     count = count + 1;
        current = current.getNext();}
108   return count;
    }
110 /**
     * Insert the input node after this node.
112  * @param node element to insert after this.
     **/
114 public void insertAfter(SceneElement node){
      // Save what "this" currently points at
116   SceneElement oldNext = this.getNext();
      this.setNext(node);
118   node.setNext(oldNext);
    }
120
    /**
122  * Return the last element in the list
     **/
124   public SceneElement last() {
        SceneElement current;
126
        current = this;
128     while (current.getNext() != null)
        {
130       current = current.getNext();
        };
132     return current;
    }
134
    /**
136  * Reverse the list starting at this,
     * and return the last element of the list.
138  * The last element becomes the FIRST element
     * of the list, and THIS goes to null.
140  **/
      public SceneElement reverse() {
142     SceneElement reversed, temp;

144     // Handle the first node outside the loop
```

```
        reversed = this.last();
146     this.remove(reversed);

148     while (this.getNext() != null)
        {
150       temp = this.last();
          this.remove(temp);
152       reversed.add(temp);
        };
154     // At this point, reversed
        // is the head of the list
156     return reversed;
      }
158
      /**
160    * Add the input node after the last node in this list.
       * @param node element to insert after this.
162    **/
      public void add(SceneElement node){
164     this.last().insertAfter(node);
      }
166
}
```

The two subclasses, SceneElementPositioned and SceneElementLayered, are really quite short. They only specify what's *different* from the superclass. The relationship between a superclass and a subclass is often called, by object-oriented designers, a *generalization-specialization relationship* (sometimes shortened to *gen-spec*). The SceneElement is the general form of a scene element, that describes how scene elements *generally* work. The two subclasses just specify how they are *special*, different from the general case (Figure 7.12).

Example Java Code: **SceneElementPositioned**

Program Example #50

```
public class SceneElementPositioned extends SceneElement {
2
  /**
4  * Make a new element with a picture as input, and
   * next as null.
6  * @param heldPic Picture for element to hold
   **/
8 public SceneElementPositioned(Picture heldPic){
    myPic = heldPic;
10  next = null;
```

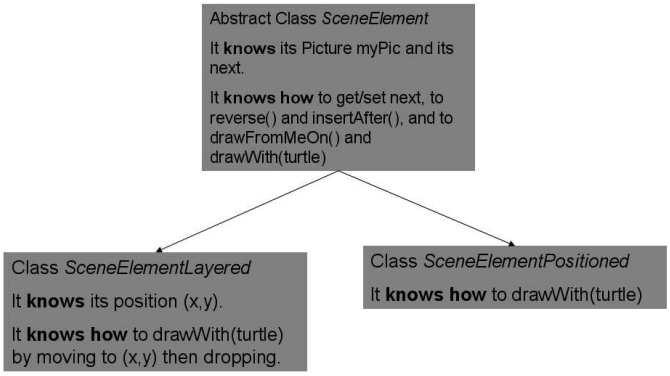

Figure 7.12: The abstract class SceneElement and its two subclasses

```
  }

  /**
   * Method to draw from this picture.
   * @param pen Turtle to use for drawing
   **/
  public void drawWith(Turtle pen) {
    pen.drop(this.getPicture());
  }
}
```

Program Example #51

Example Java Code: **SceneElementLayered**

```
public class SceneElementLayered extends SceneElement {

  /**
   * The coordinates for this element
   **/
  private int x, y;

  /**
   * Make a new element with a picture as input, and
   * next as null, to be drawn at given x,y
   * @param heldPic Picture for element to hold
   * @param xpos x position desired for element
   * @param ypos y position desired for element
   **/
```

```
15    public SceneElementLayered(Picture heldPic, int xpos, int ypos){
        myPic = heldPic;
17      next = null;
        x = xpos;
19      y = ypos;
      }
21
      /**
23     * Method to draw from this picture.
       * @param pen Turtle to draw with
25     **/
      public void drawWith(Turtle pen) {
27      // We just ignore the pen's position
        pen.moveTo(x,y);
29      pen.drop(this.getPicture());
      }
31  }
```

This structure will only make sense when we try it out. Here's a simple example of a picture drawn with both kinds of scene elements in a single linked list (Figure 7.13). Notice that the dog is *under* the flower, both of which are out of the linear sequence across the bottom.

Example Java Code: **MultiElementScene**

Program Example #52

```
    public class MultiElementScene {
2
    public static void main(String[] args){
4     // Be sure to set the media path first.
      //FileChooser.setMediaPath("D:/cs1316/mediasources/");
6
      // We'll use this for filling the nodes
8     Picture p = null;

10    p = new Picture(FileChooser.getMediaPath("swan.jpg"));
      SceneElement node1 = new SceneElementPositioned(p.scale(0.25));
12
      p = new Picture(FileChooser.getMediaPath("horse.jpg"));
14    SceneElement node2 = new SceneElementPositioned(p.scale(0.25));

16    p = new Picture(FileChooser.getMediaPath("dog.jpg"));
      SceneElement node3 = new SceneElementLayered(p.scale(0.25),50,50);
18
      p = new Picture(FileChooser.getMediaPath("flower1.jpg"));
20    SceneElement node4 = new SceneElementLayered(p.scale(0.5),10,30);
```

Figure 7.13: A scene rendered from a linked list with different kinds of scene elements

```
22      p = new Picture(FileChooser.getMediaPath("graves.jpg"));
        SceneElement node5 = new SceneElementPositioned(p.scale(0.25));
24
        node1.setNext(node2); node2.setNext(node3);
26      node3.setNext(node4); node4.setNext(node5);

28      // Now, let's see it!
        Picture bg = new Picture(600,600);
30      node1.drawFromMeOn(bg);
        bg.show();
32    }
  }
```

It is easier to see how a single turtle is being used to draw all of these elements if we change how we traverse the list with drawFromMeOn in the SceneElement class. We will simply traverse the list with the turtle's pen *down*.

* * *

Example Java Code: **Modified drawFromMeOn in SceneElement** *Program Example #53*

```
/**
 * Method to draw from this node on in the list.
 * For positioned elements, compute locations.
 * Each new element has it's lower-left corner at the lower-right
 * of the previous node. Starts drawing from left-bottom
 * @param bg Picture to draw drawing on
 **/
public void drawFromMeOn(Picture bg) {
  SceneElement current;

  // Start the X at the left
  // Start the Y along the bottom
  int currentX=0, currentY = bg.getHeight()-1;

  Turtle pen = new Turtle(bg);
  pen.setPenDown(true); // NOW, LEAVE THE PEN DOWN

  current = this;
  while (current != null)
  { // Position the turtle for the next positioned element
    pen.moveTo(currentX,currentY-current.getPicture().getHeight());
    pen.setHeading(0);

    current.drawWith(pen);
    currentX = currentX + current.getPicture().getWidth();

    current = current.getNext();
  }
}
```

The result is a picture showing the trace of where the turtle moved throughout the traversal (Figure 7.14). The pen gets created in the center, then travels down to the left corner to draw the swan, then moves right (the width of the swan) to draw the horse. The turtle pen moves into position for drawing the flower, but instead moves to the dog's saved position and draws there. The turtle moves back into place to draw the next positioned scene element, but again moves up to draw the flower (on top of a corner of the dog picture). Finally, it moves to the next position and draws

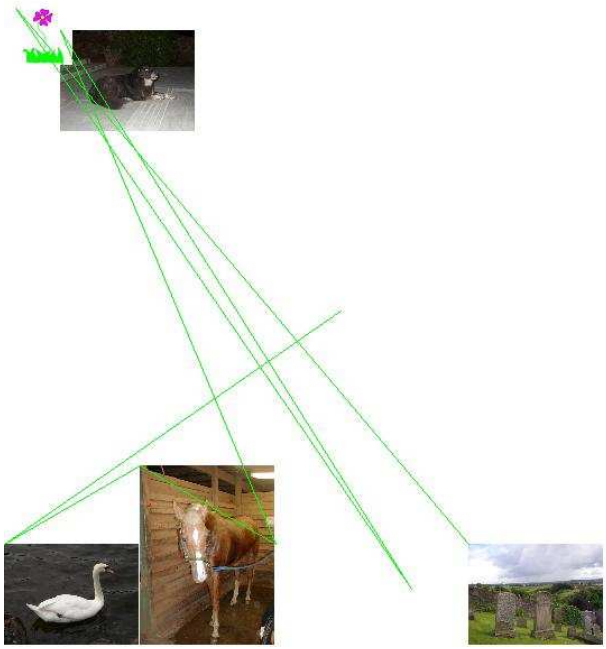

Figure 7.14: Same multi-element scene with pen traced

the graves there.

Structuring Our Multi-Element Lists

One can imagine using our new kind of multi-element lists to create complicated scenes.

- Imagine creating large sequences of objects next to one another, like trees in a forest, or orcs about to enter into battle in *The Lord of the Rings*. We could create these by inserting as many nodes as we need with SceneElementPositioned. We wouldn't want to position each of these separately—we simply want to add them all into the list and have them drawn at the right place.
- Now, you might want to position some specific characters at specific positions in the scene, such as an elf and a dwarf to battle the orcs, or a plastic spaceman getting ready to enter the scene.

A linear list is not the best way to present such a scene. You would want to keep track of this band of orcs here, and that band of orcs there, with a forest behind, and a few brave heroes getting ready to keep the horde at bay. A linear list doesn't give you an easy way of keeping track of the various pieces. A linear list is just a long list of nodes.

It would be easier to structure and manipulate the scene if one part of the linked list represented the Fifth Army of Orcs, and another part represented the forest, and the heroes were elsewhere–and if all those parts were clearly labeled and manipulable. To keep track of just that kind of structure, we are going to introduce a *scene graph*, a kind of *tree*. A tree structures a linked list into a hierarchy or clusters. A scene graph is an important data structure in defining scenes in modern computer animations. That's where we're heading next.

Ex. 2 — Create a method copyList that copies the list at **this** and returns a new list with the same elements in it.

Ex. 3 — Create a method copyList(**int** n,m) that starts at **this** as the 0th element in the list, goes to the *n*th element, and returns a new list from the *n*th to the *m*th element.

Ex. 4 — Using any of the linked lists of pictures that we created (where ordering represented linearity, or layering, or using turtles to walk the list), implement three additional methods (where firstpicturnodeinlist is a node, not actually a picture):

- firstnodeinlist .findAndReplaceRepeat(oldelement,newelement,n): Find oldelement (it's a node, not a picture, so you can look for an exact match), remove oldelement from the list, and then insert at oldelement's place n copies of the node newelement. Imagine this as implementing the special effect where the witch disappears and gets replaced with three smaller copies of the witch at the same place.

- firstnodeinlist .replaceWithModification(findelement,**int** type): Find the node findelement (a node, not a picture, so you can do an exact match), then replace it with a node containing a modified picture of the picture in findelement. The type indicates the kind of modification. If 1, negate the picture. If 2, mirror horizontal. If 3, mirror vertical. If 4, sunset. If anything else, insert grayscale. This is about changing the image in some predefined way for any node in the list.

- firstnodeinlist .replaceWithModifications(findelement,**double**[] types): Find the node findelement (a node, not a picture, so you can do an exact match), then replace it with nodes containing a modified picture of the picture in findelement. Insert as many nodes as there are entries in the types array, e.g., if there are 3 values in the array, insert 3 copies. The value in the types array indicates the kind of image modification for that element. If 1, negate the picture. If 2, mirror horizontal. If 3, mirror vertical. If 4, sunset. If anything else, insert grayscale. So, if the array was {1,2,5}, you would insert three copies of the picture in findelement the first negated, the second mirrored horizontal, and the

third grayscaled. This is an example of taking a base wildebeest and replacing it with several copies having different colors.

You can be sure that oldelement or findelement will never be equal to the firstnodeinlist.

You must also provide a class named PictureTest that has a main() method which utilizes all three of your new methods. When the grader executes the main(), it should (a) show a background with three or more pictures in it, (b) then show a new picture after using findAndReplaceRepeat, and (c) a third picture after using replaceWithModification, then (d) a final fourth picture after using replaceWithModifications.

Ex. 5 — Create a class with a main method that sets up a scene with LayeredSceneElement, then change the layering of just a *single* element using remove and insertAfter—much as we did to make the doggy run in our first animation using PositionedSceneElement.

Ex. 6 — Take any linked list implementation that we have created thus far, and recreate it as a doubly-linked list. Make sure that insertAfter and remove work, and implement insertBefore as well.

8 Abstract Data Types: Separating the Meaning from the Implementation

Chapter Learning Objectives

One of the most powerful ideas in computer science is that the *definition* of a data structure can be entirely separated from the *implementation* of the data structure. This idea is powerful because it allows us to design and implement *other* code that uses the given data structure (1) without knowing the implementation of the data structure and (2) even if the implementation of the data structure changes.

The computer science goals for this chapter are:

- To explain the separation of definition and implementation.
- To explain the definition of the queue and offer two implementations of those.
- To explain the definition of the stack and offer two implementations of those.

The media learning goals for this chapter are:

- To have a faster way of reversing the elements in a list by using a stack.

8.1 Introducing the Stack

A *stack* is a data structure that corresponds to how a stack (literally!) of plates work. Imagine a stack of fine plates (Figure 8.1). You only put new plates on a stack from the top. You *can* insert plates in the middle, but not easily, and you risk scraping the plates. You only remove plates from a stack from the top. Removing from the middle or (worse yet) the bottom is dangerous and risks damaging the whole stack.

Those basic notions of how a physical stack work correspond to how the stack data structure works. Think of a stack as a list of elements—just a sequence of items. (Are the items in a linked list? An array? We

Figure 8.1: A pile of plates—only put on the top, never remove from the bottom

are *explicitly* not saying at this point.) The first item pushed on the stack stays at the bottom of the stack. Later items are put at the top of the stack (Figure 8.2).

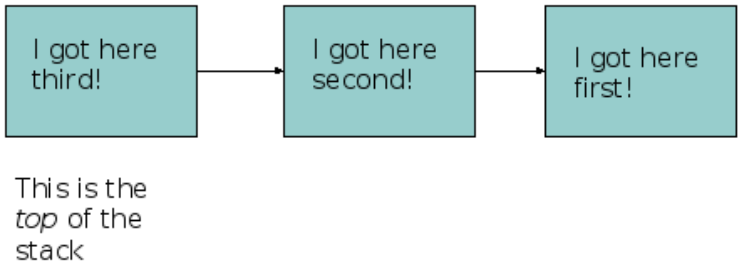

Figure 8.2: Later items are at the head (top) of stack

New items are added at the head of the stack (Figure 8.3). When a new item is removed from the stack, it is always the last, newest item in the list which is removed first (Figure 8.4). For that reason, a stack is sometimes also called a *LIFO list*—Last In, First Out. The last item inserted into the stack is the first one back out.

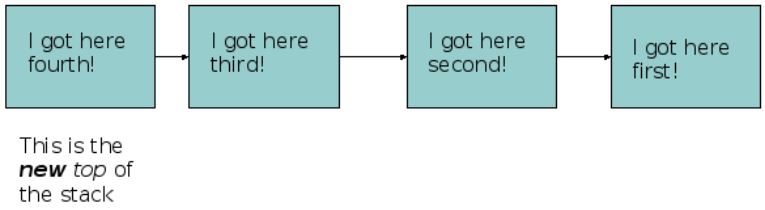

Figure 8.3: New items are inserted at the top (head) of the stack

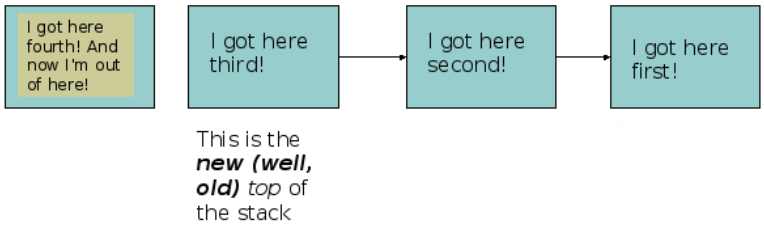

Figure 8.4: Items are removed from the top (head) of a stack

Defining an Abstract Data Type

A stack is an example of an *Abstract Data Type*. An abstract data type defines the operations, structure, and behavior of a data structure *without* specifying how those operations, structure, and behavior are actually implemented. By separating the concerns of *what* is supposed to happen from *how* it is supposed to happen, the task of programming with that data type is made easier.

There are formal ways of defining an abstract data type (ADT). These formal methods use symbols and logical equations to define behavior and structure without getting into the implementation. Those aren't our focus here. Instead, we will focus on a general notion of how the ADT works.

What should someone be able to do with a stack data structure? Here is a list of basic operations for a stack with a brief description of what each does. If we got these right, these should mesh with the intuitive understanding of stacks described previously.

- push(anObject): Tack a new object onto the top of the stack
- pop(): Pull the top (head) object off the stack.
- peek(): Get the top of the stack, but dont remove it from the stack.
- size(): Return the size of the stack
- empty(): Returns true if the size of the stack is zero—nothing is left in the stack.

Computer Science Idea: Separation of Concerns

By separating the definition of the data structure from the implementation, we can use the new data structure in programs without regard for implementation. An important implication is that the implementation can be changed (improved, upgraded, whatever) and the programs that use the data structure need not change *at all*!

For example, here is a program that uses a stack, PictureStack, that contains SceneElement nodes.

Program Example #54

Example Java Code: **Testing program for a PictureStack**

```
public class PictureStackTest {
 public static void main(String [] args){
   PictureStack stack = new PictureStack();
   SceneElementPositioned element = null;

   // Push 3 pictures on the stack: Swan, temple, horse
   element=new SceneElementPositioned(
      new Picture(FileChooser.getMediaPath("swan.jpg")));
   stack.push(element);
   element=new SceneElementPositioned(
      new Picture(FileChooser.getMediaPath("temple.jpg")));
   stack.push(element);
   element=new SceneElementPositioned(
      new Picture(FileChooser.getMediaPath("horse.jpg")));
   stack.push(element);

   //Pop one -- should be the horse
   stack.pop().getPicture().show()

   //Push another -- the turtle
   element=new SceneElementPositioned(
      new Picture(FileChooser.getMediaPath("turtle.jpg")));
   stack.push(element);

   //Pop another -- should be the turtle
   stack.pop().getPicture().show();

   //Pop another -- should be the temple
   stack.pop().getPicture().show();
 }
```

```
}
```

Given that we're pushing and popping instances of SceneElementPositioned, you have probably guessed that the internal implementation is a linked list. It need not be. The PictureStack could be implemented as an array of SceneElement. The important point is this: *It doesn't matter!* No matter how PictureStack is implemented, the above example *should just work*, as long as it meets the definition of a stack.

The idea of separation of concerns is actually built into Java as a construct. In Java, one can define an Interface. An **interface** is akin to an **abstract class** in that it defines a set of methods and no one can instantiate an **interface**. An **interface** is just the definition of the operations of an abstract data type, like those we just defined for a stack. A particular class can declare that it **implements** a given **interface**. That implementation is then a promise, a contract with programs that use the particular class—that the methods in the **interface** are implemented and implemented properly so that the operation of the data type works.

Implementation of a Stack

At this point, our discussion of abstract data types is rather abstract—it's all definition and no implementation. Let's implement PictureStack to see how it might work. First, let's define the basic structure of the class.

Example Java Code: **PictureStack**

Program Example #55

```
public class PictureStack {

  /** Where we store the elements */
  private SceneElement elements=null;

  /// Constructor ////
  public PictureStack() {
    // If our SceneElement had an empty first
    // node, we'd create it here.
  }

// Methods go here
}
```

We can already see that we are going to have some kind of linked list of SceneElement instances. Let's define those basic methods.

* * *

Program Example #56

Example Java Code: **PictureStack—push, peek, and pop**

```
//// Methods ///
public void push(SceneElement element){
  if (elements == null)
  {// First new element on the stack
    // becomes the one that we point at
    elements = element;}
  else
  { // New elements go at the front
    //The rest get added to the front
    //by making the new one point to the
    //rest of the list, then change
    //the pointer to the new front.
    element.setNext(elements);
    elements = element;}

}

//Top element is the first one
public SceneElement peek(){
  return elements;
}

// Get the first one to return,
// then point to the second one
public SceneElement pop(){
  SceneElement toReturn = this.peek();
  elements=elements.getNext();
  return toReturn;
}
```

We are going to use the variable elements to point to the head of the list. To push a new element on the list is to make the new item point to the rest of the list, and to make elements point to the new element. To peek is simply to return whatever elements points at. Pop is a matter of getting the peek, making elements point to the next element (elements.getNext()), and returning what was previously peeked.

The other two methods needed to match the definition of a stack follow.

* * *

am
ple #57

Example Java Code: **PictureStack—size and empty**

```
public int size(){return elements.count();}

/** Empty? */
public boolean empty() {return this.size() == 0;}
```

Given this definition, our PictureStackTest class should work correctly now. However, there were more ways to implement the stack. It's worthwhile understanding more than one way to define the stack.

Multiple Implementations of a Stack

Just to make it simpler for us to trace, let's consider the implementation of a class Stack that stores simple strings. If we implement Stack correctly, the below should work:

```
  Welcome to DrJava.
> Stack stack = new Stack()
> stack.push("This")
> stack.push("is")
> stack.push("a")
> stack.push("test")
> stack.size()
4
> stack.peek()
"test"
> stack.pop()
"test"
> stack.pop()
"a"
> stack.pop()
"is"
> stack.pop()
"This"
> stack.pop()
java.util.NoSuchElementException:
```

Should that last pop, when there was nothing left in the stack, have generated that error? If not, what error should it have generated? Java does give us the opportunity to define our own exceptions and **throw** that exception (e.g., cause it to stop execution and appear in the Interactions Pane or console). We will explore exceptions in a later chapter.

The two most common implementations of stacks use linked lists and arrays. Let's look at each of those. First, we will use a stack implementation with a linked list, where we will use Java's provided implementation

of a linked list. Yes, Java has a linked list! How is it implemented? Is it a singly or doubly linked list? We don't know and we don't care—that's separation of concerns. A bigger question is why we haven't been using Java's linked list all along. We'll explain that when we get to simulations.

Program Example #58

Example Java Code: **Stack implementation with a linked list**

```
import java.util.LinkedList; // Need for LinkedList

public class Stack {

  /** Where we store the elements */
  private LinkedList elements;

  /// Constructor ////
  public Stack() {
    elements = new LinkedList();
  }

 //// Methods ///
  public void push(Object element){
    // New elements go at the front
    elements.addFirst(element);
  }

  public Object peek(){
    return elements.getFirst();
  }

  public Object pop(){
    Object toReturn = this.peek();
    elements.removeFirst();
    return toReturn;
  }

  public int size(){return elements.size();}

  /** Empty? */
  public boolean empty() {return this.size() == 0;}
}
```

How it works: In this implementation, we have decided that the head of the stack is the first item in the linked list. Java's linked list implementation provides a getFirst and a addFirst method—the former is the heart of peek and the latter is how we push. Since we have removeFirst too, that's

how we pop. It is interesting that the definition of empty is identical in both implementations we have seen of stacks.

Java's linked list implementation can actually store any object at all. Its implementation works around the class Object. Every class (even if it declares no superclass) is a subclass of Object. Thus, an Object variable can hold anything at all.

If we use this implementation of Stack in the example earlier, it will work as expected. Here's a different implementation, using an array. We will use an array of Object instances, so that we can store anything we want in our stack. In this example, the class Stack2 (use it just like Stack) has an index in the array for a top.

Example Java Code: **Stack implementation with an array** *Program Example #59*

```
/**
 * Implementation of a stack as an array
 **/
public class Stack2 {

  private static int ARRAYSIZE = 20;

  /** Where we'll store our elements */
  private Object[] elements;

  /** Index where the top of the stack is */
  private int top;

 /// Constructor ////
  public Stack2() {
    elements = new Object[ARRAYSIZE];
    top = 0;
  }
  //METHODS GO HERE
}
```

Here, the variable elements is an array of objects. We have a **static** variable that declares that our array will have at most 20 elements in it. To create a Stack2, we create an array of Objects, and set the top at element index zero.

Example Java Code: **Stack implementation with an array—methods** *Program Example #60*

```
  //// Methods ///
public void push(Object element){
  // New elements go at the top
  elements[top]=element;
  // then add to the top
  top++;
  if (top==ARRAYSIZE){
    System.out.println("Stack overflow!");
  }
}

public Object peek(){
  if (top==0){
    System.out.println("Stack empty!");
    return null;
  } else{
    return elements[top-1];}
}

public Object pop(){
  Object toReturn = this.peek();
  top--;
  return toReturn;
}

/** Size is simply the top index */
public int size(){return top;}

/** Empty? */
public boolean empty() {return this.size() == 0;}
```

How it works: In this implementation, the variable top is an index to the next *empty* element in the array. The size is then the same as the index. To insert a new element, we set the value at elements[top] and increment top. The top value is at elements[top−1]. To remove an element, we decrement top.

We can now test Stack2 and find that it works remarkably like our Stack. When we first create an instance of Stack2, it looks like Figure 8.5. After we push ''Matt" on the stack, it looks like Figure 8.6—the variable top always points at the *next* element on the stack. We then push ''Katie'' and ''Jenny", then pop ''Jenny", resulting in Figure 8.7—Jenny is still in the array, but since top points at that element, Jenny will be over-written with the next push().

```
  Welcome to DrJava.
> Stack2 stack = new Stack2();
> stack.push("Matt")
> stack.push("Katie")
```

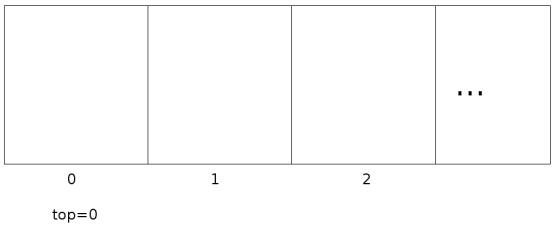

Figure 8.5: An empty stack as an array

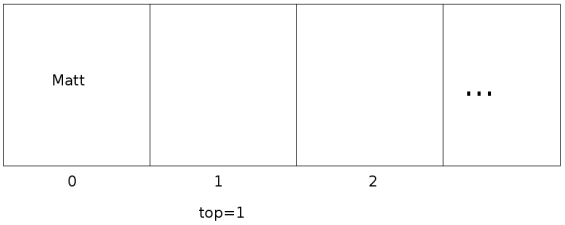

Figure 8.6: After pushing Matt onto the stack-as-an-array

```
> stack.push("Jenny")
> stack.size()
3
> stack.peek()
"Jenny"
> stack.pop()
"Jenny"
> stack.pop()
"Katie"
> stack.pop()
"Matt"
> stack.pop()
Stack empty!
null
```

There are problems with Stack2 as an implementation of a stack. For example, what happens if you need more than 20 elements in your stack? And actually, it's 19 elements—top always points at an unused cell. However, within the limitations of Stack2 (e.g., as long as you have fewer than 20 elements in the stack), it is a perfectly valid implementation of a stack. Both Stack and Stack2 are implementations of the same stack ADT.

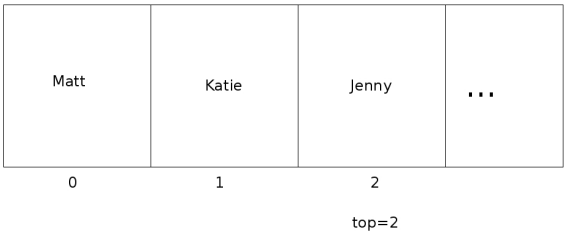

Figure 8.7: After pushing Katie and Jenny, then popping Jenny

Uses of a Stack

We haven't seen enough algorithms yet to be able to describe many uses of stacks, though they are quite useful. For example, the process of converting an equation like $4 * \sin(x/2)$ into operations that a computer can execute uses a stack. There is one use of a stack that we have already seen a need for—reversing a list.

Below is the method that we wrote previously for reversing a list.

Program Example #61

Example Java Code: **Reverse a list–repeated**

```
/**
  * Reverse the list starting at this,
  * and return the last element of the list.
  * The last element becomes the FIRST element
  * of the list, and THIS points to null.
  **/
   public LayeredSceneElement reverse() {
   LayeredSceneElement reversed, temp;

   // Handle the first node outside the loop
   reversed = this.last();
   this.remove(reversed);

   while (this.getNext() != null)
   {
     temp = this.last();
     this.remove(temp);
     reversed.add(temp);
   };

   // Now put the head of the old list on the end of
   // the reversed list.
   reversed.add(this);
```

```
    // At this point, reversed
    // is the head of the list
    return reversed;
  }
```

It's awfully inefficient. To get each item in the list, it goes to the last() (which requires touching every element in the list), removes it (which involves touching every node in order to find the one before the one we want to remove), and then adds it to the end of the reversed list (by walking all the elements of the reversed list to get the last). Overall, touching each node of n nodes requires touching every other node at least once, meaning that it's an $O(n^2)$ algorithm.

We can do this much faster with a stack. We simply walk the list pushing everything onto the stack. We pop them off again, and they assemble in reversed order.

Example Java Code: **Reverse with a stack** *Program Example #62*

```
/**
* Reverse2: Push all the elements on
* the stack, then pop all the elements
* off the stack.
**/
 public LayeredSceneElement reverse2() {
   LayeredSceneElement reversed, current, popped;
   Stack stack = new Stack();

   // Push all the elements on the list
   current=this;
   while (current != null)
   {
     stack.push(current);
     current = current.getNext();
   }

   // Make the last element (current top of stack) into new first
   reversed = (LayeredSceneElement) stack.pop();

   // Now, pop them all onto the list
   current = reversed;
   while (stack.size()>0) {
     popped=(LayeredSceneElement) stack.pop();
     current.insertAfter(popped);
     current = popped;
   }
```

```
        return reversed;
    }
```

You will notice that we have to cast the popped elements. Our Stack returns instances of Object. To get them to be able to access methods like getNext() and insertAfter(), we have to tell Java that these are actually our linked list nodes. So we cast, like popped=(LayeredSceneElement) stack.pop();.

There is a big difference in time of execution here. Each node is touched exactly twice—once going on the stack, and once coming off. There is no last nor remove here to cause us extra traversals of the list. This is an $O(n)$ algorithm—much faster than the last one.

Does that time really matter? If you really needed to reverse a linked list, does $O(n)$ or $O(n^2)$ matter? Couldn't you just recreate the linked list, even, rather than reverse it? There are situations where the size of the list does matter.

Consider a scene from Pixar's *The Incredibles*, where the monorail enters the bad guy's lair through a waterfall that parts (incredible!) to allow the monorail entry. Each droplet in that scene was modeled as an object that was nearly transparent—it showed up only 1 millionth of a bit of color. Thus, everwhere that looks white (which is nearly everywhere in a waterfall scene) is actually over one million objects stacked up at that spot on the screen.

Now, imagine that those droplets are stored in a linked list, and the director says "Ooh! Oooh! Now, let's show the waterfall from the *inside* as the monorail passes through!" At that point, you have to reverse the linked list. You could recreate the list—but that is a big list to recreate. If your algorithm is $O(n)$, that's a million steps per screen element. That's a lot of processing, but not insurmountable. If your algorithm is $O(n^2)$, that's a million-*squared* operations per screen element—one trillion operations per pixel. Computers are fast. Computers are not infinitely fast.

8.2 Introduction to Queues

A *queue* is another useful abstract data type. A queue models what the British call "a queue," and what we in the United States call "a line." A queue is a *FIFO list*, *First In First Out list*. The first one in the line is the first one served. When someone new comes into the line, the bouncer at the front of the line yells out, "Get in the back of the line!" New elements enter at the end, not at the front, never in the middle (that's called "cutting in the line".

Unlike a stack, which just has a *head* or *top*, a queue has both a *head* and a *tail* (Figure 8.8). Elements are popped from the *head* (Figure 8.9). When a new element comes in, it gets pushed onto the queue at the *tail* (Figure 8.10).

The basic operations of a queue are pretty similar to those of a stack.

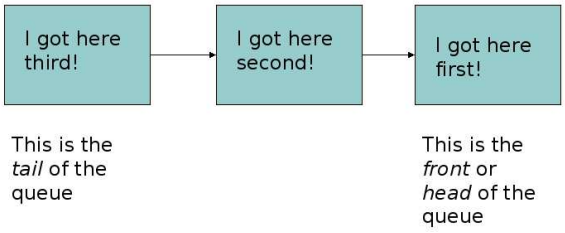

Figure 8.8: A basic queue

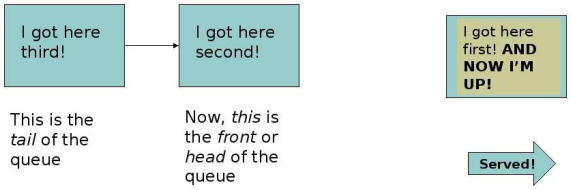

Figure 8.9: Elements are removed from the top or head of the queue

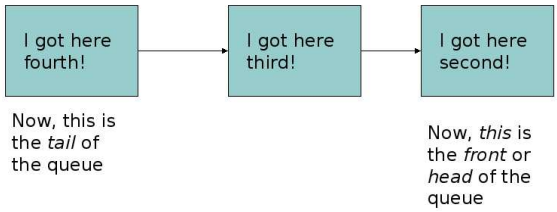

Figure 8.10: New elements are pushed onto the tail of the queue

- push(anObject): Tack a new object onto the tail of the queue
- pop(): Pull the top (head) object off the queue.
- peek(): Get the head of the queue, but dont remove it from the queue.
- size(): Return the size of the queue
- empty(): Return true or false, if the size of the queue is zero.

We should be able to use a queue like this:

```
> Queue line = new Queue();
> line.push("Fred");
> line.push("Mary");
> line.push("Jose");
> line.size()
```

```
3
> line.peek()
"Fred"
> line.pop()
"Fred"
> line.peek()
"Mary"
> line.pop()
"Mary"
> line.peek()
"Jose"
> line.pop()
"Jose"
> line.pop()
java.util.NoSuchElementException:
```

Implementing a Queue

We can implement a queue using either a linked list, or an array—just like a stack. A linked list implementation of a queue is again made very easy by Java's LinkedList implementation.

Program Example #63

Example Java Code: **Queue implemented as a linked list**

```
import java.util.*; // LinkedList representation

/**
 * Implements a simple queue
 **/
public class Queue {
  /** Where we'll store our elements */
  public LinkedList elements;

  /// Constructor
  public Queue(){
    elements = new LinkedList();
  }

 /// Methods

  /** Push an object onto the Queue */
  public void push(Object element){
    elements.addFirst(element);
  }

  /** Peek at, but don't remove, top of queue */
  public Object peek(){
```

```
    return elements.getLast();}

  /** Pop an object from the Queue */
  public Object pop(){
    Object toReturn = this.peek();
    elements.removeLast();
    return toReturn;
  }

  /** Return the size of a queue */
  public int size() { return elements.size();}

  /** Empty? */
  public boolean empty() {return this.size() == 0;}
}
```

How it works: In this implementation of a queue, the elements are stored in an instance of Java's LinkedList. The front of the linked list is the tail. The last of the linked list is the head. (That may seem backwards, but any arrangement of head/tail to front/back is arbitrary. That one might find an implementation confusing is yet another good reason for separating the concerns.) To pop the stack then requires removing the last (removeLast), and to push is adding to the first (addFirst).

The critical issue in implementing a queue is that, from the perspective of the use of the queue, the implementation doesn't matter. As long as those same basic operations are available, the implementation of the queue can be swapped out, improved, made faster (or slower, for that matter)—and it just doesn't matter to the program using the queue.

An obvious alternative to the linked list implementation seen above is an implementation based on an array. Implementing a queue using an array to store the elements is much the same as implementing a stack with an array except that, as before, we need both a head and a tail.

Example Java Code: **Queue implemented as an array**

Program Example #64

```
/**
 * Implements a simple queue
 **/
public class Queue2 {

  private static int ARRAYSIZE = 20;

  /** Where we'll store our elements */
  private Object[] elements;
```

```
  /** The indices of the head and tail */
  private int head;
  private int tail;

  /// Constructor
  /** Both the head and the tail point at the same empty cell **/
  public Queue2(){
    elements = new Object[ARRAYSIZE];
    head = 0;
    tail = 0;
  }

 /** Push an object onto the Queue */
  public void push(Object element){
    if ((tail + 1) >= ARRAYSIZE) {
      System.out.println("Queue underlying implementation failed");
    }
    else {
      // Store at the tail,
      // then increment to a new open position
    elements[tail] = element;
    tail++; } }

  /** Peek at, but don't remove, top of queue */
  public Object peek(){
    return elements[head];}

  /** Pop an object from the Queue */
  public Object pop(){
      Object toReturn = this.peek();
      if (((head + 1) >= ARRAYSIZE) ||
        (head > tail)) {
      System.out.println("Queue underlying implementation failed.");
      return toReturn;
    }
    else {
      // Increment the head forward, too.
      head++;
      return toReturn;}}

  /** Return the size of a queue */
  public int size() { return tail-head;}

  /** Empty? */
  public boolean empty() {return this.size() == 0;}
}
```

* * *

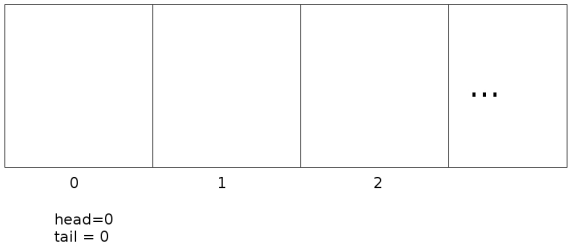

Figure 8.11: When the queue-as-array starts out, head and tail are both zero

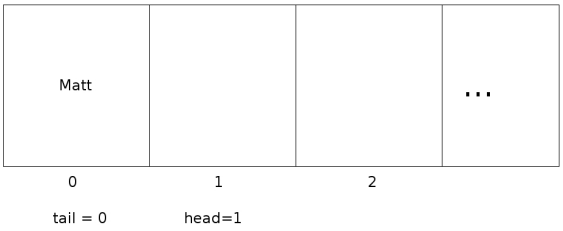

Figure 8.12: Pushing Matt onto the queue moves up the head to the next empty cell

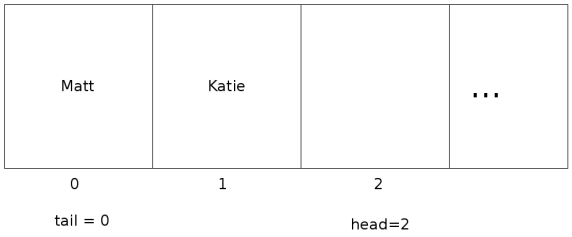

Figure 8.13: Pushing Katie on moves the head further right

How it works: Each of the head and tail variables holds in index number on the underlying array. The size of the queue is the difference between the *head* and the *tail*. When the queue is first created, both the *head* and the *tail* are zero, the first cell in the array (Figure 8.11). When we push something on, the *tail* increments to the next empty cell in the array (which has been implemented as the head variable in this implementation, Figure 8.12 and Figure 8.13). Popping from the *head* increments it (again, variable tail in this implementation, Figure 8.14).

The problems of implementing queues as arrays are even greater than the ones with implementing stacks as arrays, because now we have both a

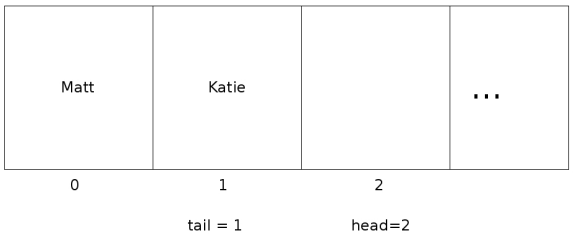

Figure 8.14: Popping Matt moves the tail up to Katie

head and a tail to keep track of. Notice that the head and tail keep moving along the array, so the implementation can't even store 20 elements at once. It can only store 20 elements *ever*—once we get past 20, both head and tail are at the end of the array. There are implementations of queues in arrays that are smarter than this one. For example, there's no reason why we can't wrap around the queue—once we increment past the end, just start re-using cells at the beginning of the array. It's a little trickier to make sure that the head and tail don't overlap one another. Then, the 20 element limitation is just the number of items at once, which isn't unreasonable.

We haven't seen uses of the queue yet. Queues will become very important when we create discrete event simulations. When several agents want the same resource (e.g., when customers line up at the cashier station, when moviegoers line up at the ticket office), they form a line. We will need queues for modeling those lines.

Ex. 7 — Change the implementation of the queue as an array so that the head and tail variables match the head and tail concepts.

Ex. 8 — Change the implementation of the queue as a linked list so that the head is at the front and the tail is at the end.

Ex. 9 — Reimplement the queue in an array with wraparound—when the head or tail get to the end of the array, they wrap around to the front.

Part III

Trees: Hierarchical Structures for Media

9 Trees of Images

Chapter Learning Objectives

Having worked with linked lists of images, we are in a position to think about non-linear lists of images. By moving to trees, we can represent structure and hierarchy.

The computer science goals for this chapter are:

- To create and use trees to represent collections of images.
- To construct and traverse trees.

The media learning goals for this chapter are:

- To introduce the structure of a scene graph, which is a common animation data structure.
- To use trees to create an animation.

9.1 Representing scenes with trees

A list can only really represent a single dimension–either a linear placement on the screen, or a linear layering front-to-back. A full scene has multiple dimensions. More importantly, a real scene has an organization to it. There's the village over there, and the forest over here, and the squadron of Orcs emerging from the scary cave mouth to the north. Real scenes *cluster*—there is structure and organization to them.

Where we left our efforts to create a dynamic data structure for representing scenes, we had implemented a special kind of tree where some nodes layered themselves at a particular (x, y), and other nodes just laid themselves out left-to-right. One problem with this structure is that it's linear—none of the structure or organization we would want to model is available in a linear linked list. A second problem is an issue of *responsibility*. Should a picture know where it is going to be drawn? Shouldn't it just be drawn wherever it's told to be drawn—whether that's in a long lin-

ear list like long lines of Orcs in *The Lord of the Rings* movies[1], or whether it's particularly positioned like a specific house, tree, or Hobbit.

Computer Science Idea: Distribution of Responsibility

A key idea in object-oriented programming is distributing responsibility throughout the collection of objects in a model. Each object should only know what it needs to know do its job, and its methods should just be sufficient to implement that job.

We can represent an entire scene with a tree. Computer scientists call the tree that is rendered to generate an entire scene a *scene graph*. Scene graphs are a common data structure representing three-dimensional scenes. An interesting aspect of scene graphs is that they typically embed operations within the branches of the tree which effect rendering of their children. Figure 9.1 is a simple scene graph[2] with branches that *rotate* in three dimensions their children elements. Figure 9.2 is a more sophisticated scene graph[3] based on the *Java 3-D* libraries—you'll see that it also represents more sophisticated aspects of rendering the scene, like where the lighting is and implementing *translations* that move the drawing of the children to a particular place on the screen.

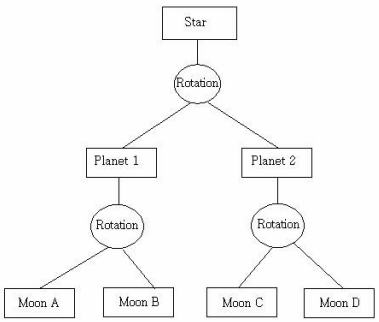

Figure 9.1: A simple scene graph

We are going to use scene graphs to represent a simple two-dimensional movie. A scene graph is a kind of tree. We are going to use our tree to cluster and organize our scene, and we will use operations in the branches of the tree to help define how the scene should be rendered.

[1] Do you think someone positioned each of those thousands of Orcs by hand? Or something auto-positioned them?

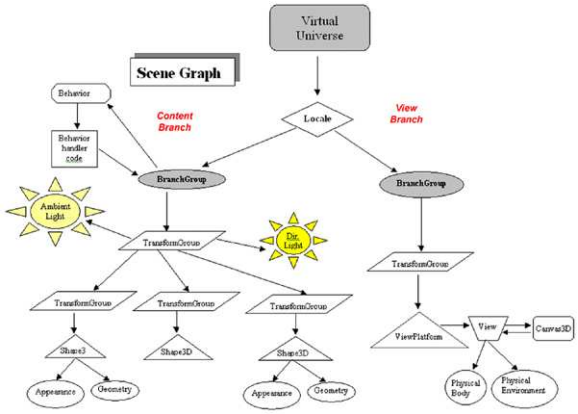

Figure 9.2: A more sophisticated scene graph based on Java 3-D

9.2 Our First Scene Graph: Attack of the Killer Wolvies

Here is the story that we will be rendering with our first scene graph. The peaceful village in the forest rests, unsuspecting that a pack of three blood-thirsty doggies, er, fierce wolvies are sneaking up on it (Figure 9.3). Closer they come, until the hero bursts onto the scene (Figure 9.4)! The fear-stricken wolvies scamper away (Figure 9.5).

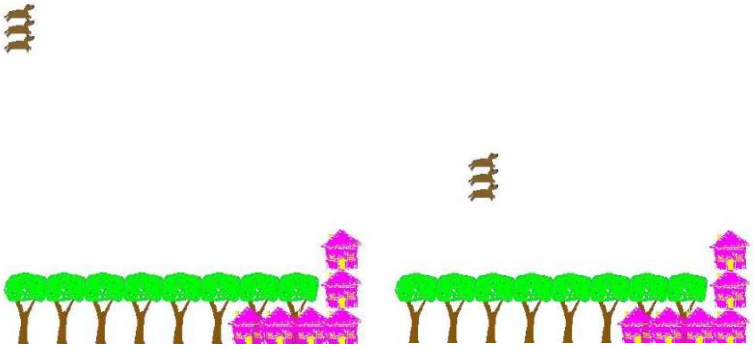

Figure 9.3: The nasty wolvies sneak up on the unsuspecting village in the forest

This scene is described as a scene graph (Figure 9.6). There is a root object, of class Branch. Each of the individual pictures are instances of BlueScreenNode which are kinds of PictNode (Picture Nodes) that use chromakey ("blue screen") for rendering themselves onto the screen. The po-

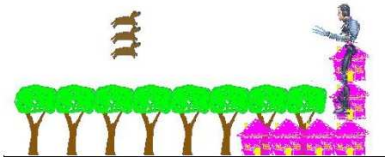

Figure 9.4: Then, our hero appears!

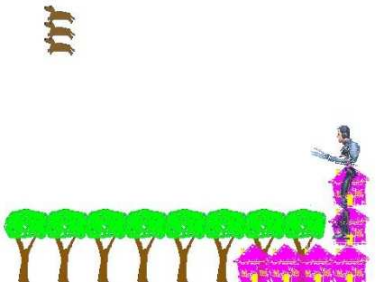

Figure 9.5: And the nasty wolvies scamper away

sition of nodes is done with MoveBranch branches. Some of the objects are laid out vertically (like the wolvies) using a VBranch instance, and others horizontally (like the forest) using a HBranch instance.

This scene graph underlying this scene is quite clearly a tree (Figure 9.7). There is a *root* at the top of the tree that everything is connected to. Each node has at most one *parent node*. There are *branch nodes* that have *children nodes* connected to them. At the ends of each branch, there are *leaf nodes* that have no children. In our scene graph, the leaves are all nodes that draw something. The branches collect the children, and thus, structure the scene. In addition, the branches in the scene graph *do* something.

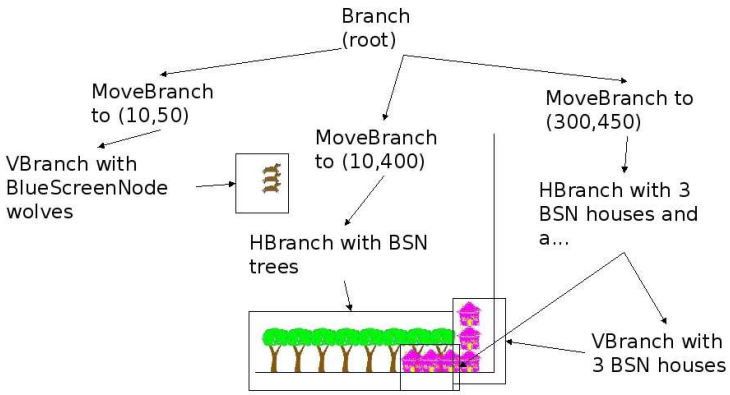

Figure 9.6: Mapping the elements of the scene onto the scene graph

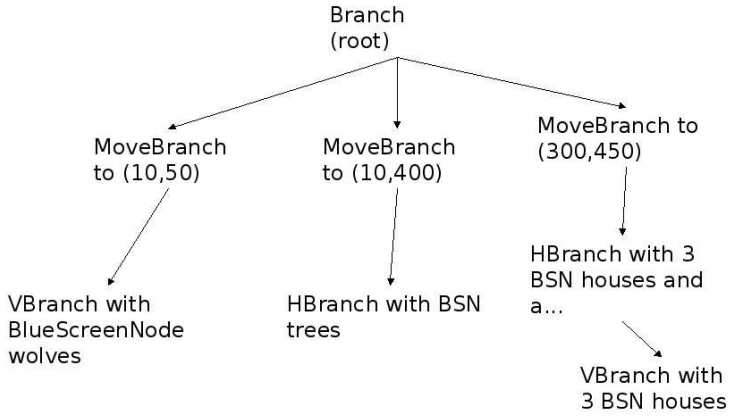

Figure 9.7: Stripping away the graphics—the scene graph is a tree

9.3 The Classes in the SceneGraph

The heart of the classes in this scene graph implementation is DrawableNode. All nodes and branches inherit from DrawableNode (Figure 9.8), an abstract superclass. The class DrawableNode defines how to be a node in a linked list—it defines next, and it defines how to add, insertAfter, and the other linked list operations. Most importantly, DrawableNode defines how to *draw* the node—albeit, abstractly.

DrawableNode defines how to drawOn a given background picture (Program
Program
Example #66 (page 208)). It simply creates a turtle and draws the node with the turtle (drawWith). The method drawWith is abstract. The definition of how any particular node actually draws itself is left to the super-

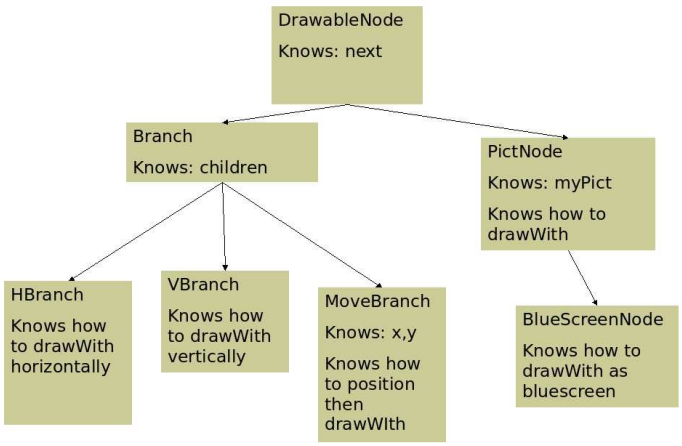

Figure 9.8: Hierarchy of classes used in our scene graph

classes.

Program Example #65

Example Java Code: **The drawing part of DrawableNode**

```
/**
 * Use the given turtle to draw oneself
 * @param t the Turtle to draw with
 **/
abstract public void drawWith(Turtle t);
// No body in the superclass

/**
 * Draw on the given picture
 **/
public void drawOn(Picture bg){
  Turtle t = new Turtle(bg);
  t.setPenDown(false);
  this.drawWith(t);
}
```

* * *

Common Bug: Class structure $\neq$ object structure

It's easy to get confused between the tree of classes in Figure 9.8 and the tree of objects in Figure 9.7. The tree of classes describes which classes inherit from which other classes, where DrawableNode is the root of the tree, the superclass or parent class of all the other classes in hierarchy. *Objects* created from these classes do form a tree (that's why we made those classes), just not the same tree. The trees don't represent the same things. The tree in Figure 9.7 represents a scene—it doesn't say anything about inheritance. A key observation is that there are several instances of the same class in the scene graph Figure 9.7, though each class appears only once in the class hierarchy Figure 9.8.

DrawableNode has two child classes—Branch and PictNode. Branch and its subclasses know how to deal with children. A Branch knows how to tell all of its children to draw, and then ask its siblings to draw. PictNode and its subclass, BlueScreenNode know how to deal with drawing pictures, the leaves of the trees. A PictNode holds a picture, and draws its picture by simply asking the turtle pen to drop the picture on the background. A BlueScreenNode has a picture, via inheritance from PictNode, but uses chromakey to put the picture onto the background.

Subclasses of Branch are about positioning and ordering the children of the branch.

- A MoveBranch positions the pen to a particular place before asking the children to draw. The MoveBranch knows x and y variables for where it should start drawing. An instance of MoveBranch is useful for positioning part of the scene.

- The branches VBranch and HBranch do automatic positioning of the children. A VBranch lays out its children vertically, and a HBranch lays out its children horizontally. Both add a gap variable for how much space to skip between children.

Thus, a MoveBranch with a PictNode or BlueScreenNode essentially does what a SceneElementLayered instance does—draw a particular picture at a particular place on the frame. First elements drawn appear below later elements in the tree. A VBranch or HBranch instance with picture nodes lets you do what a SceneElementPositioned instance does—automatic positioning of a picture. Our scene graph implementation, then, has all the capabilities of our earlier linked list, with the addition of structuring.

9.4 Building a scene graph

Let's walk through the WolfAttackMovie class, to show an example of using these classes to construct a scene graph and then create a movie that is so bad that not even the "Rotten Tomatoes" website would review it.

Program Example #66

Example Java Code: **Start of WolfAttackMovie class**

```
public class WolfAttackMovie {
  /**
   * The root of the scene data structure
   **/
  Branch sceneRoot;

  /**
   * FrameSequence where the animation
   * is created
   **/
  FrameSequence frames;

  /**
   * The nodes we need to track between methods
   **/
  MoveBranch wolfentry, wolfretreat, hero;
```

It makes sense that an instance of WolfAttackMovie will need to know the root of its scene graph, sceneRoot, and that it would be an instance of Branch. It also makes sense that a WolfAttackMovie instance will need to know a FrameSequence instance for storing and playing back the frames of the memory. What probably does not make sense is why there are three MoveBranch instances defined as instance variables for WolfAttackMovie.

It's not good object-oriented programming practice—rather, we placed the variables there to deal with scope between methods. Within WolfAttackMovie, we have a method setUp which creates the scene graph, and a later method renderAnimation which creates all the frames. To change the position of some elements in the scene, we will change the (x, y) position of the corresponding MoveBranch instances. How do we find the right MoveBranch instances to, for example, move the wolves closer to the village. Option one is to acceess the right branch through the root: searching the children and nexts to find it. Option two is to store the MoveBranch reference in an instance variable that is then within scope of *both* setUp and renderAnimation, so that we can create it in setUp and change it in renderAnimation. We're using option two here. It's not a great idea to use instance variables to

simply solve scoping problems. The advantage of option two is that it is simple.

The setUp method is large in WolfAttackMovie. It involves creating all the branches that we will need in the tree, which is a larger task than simply creating the first scene.

Example Java Code: **Start of setUp method in WolfAttackMovie** *Program Example #67*

```
/**
 * Set up all the pieces of the tree.
 **/
public void setUp(){
  Picture wolf = new Picture(FileChooser.getMediaPath("dog-blue.jpg"));
  Picture house = new Picture(FileChooser.getMediaPath("house-blue.jpg"));
  Picture tree = new Picture(FileChooser.getMediaPath("tree-blue.jpg"));
  Picture monster = new Picture(FileChooser.getMediaPath("monster-face3.jpg"));

  //Make the forest
  MoveBranch forest = new MoveBranch(10,400); // forest on the bottom
  HBranch trees = new HBranch(50); // Spaced out 50 pixels between
  BlueScreenNode treenode;
  for (int i=0; i < 8; i++) // insert 8 trees
  {treenode = new BlueScreenNode(tree.scale(0.5));
    trees.addChild(treenode);}
  forest.addChild(trees);

  // Make the cluster of attacking "wolves"
  wolfentry = new MoveBranch(10,50); // starting position
  VBranch wolves = new VBranch(20); // space out by 20 pixels between
  BlueScreenNode wolf1 = new BlueScreenNode(wolf.scale(0.5));
  BlueScreenNode wolf2 = new BlueScreenNode(wolf.scale(0.5));
  BlueScreenNode wolf3 = new BlueScreenNode(wolf.scale(0.5));
  wolves.addChild(wolf1);wolves.addChild(wolf2);wolves.addChild(wolf3);
  wolfentry.addChild(wolves);
```

How it works: The method setUp creates the pictures that we will need in the movie, then defines the forest branch of the tree (Figure 9.9). The code above creates the MoveBranch instance stored in the variable forest It creates an HBranch named trees that will hold all the trees. Each of the BlueScreenNode instances for each tree is created and named treenode. As the trees are created, they are added as children of the trees branch. Finally, the trees branch is added as a child of the forest.

Next, we create the wolves. There's a critical difference between creating the MoveBranch for the wolfentry versus the MoveBranch for the forest.

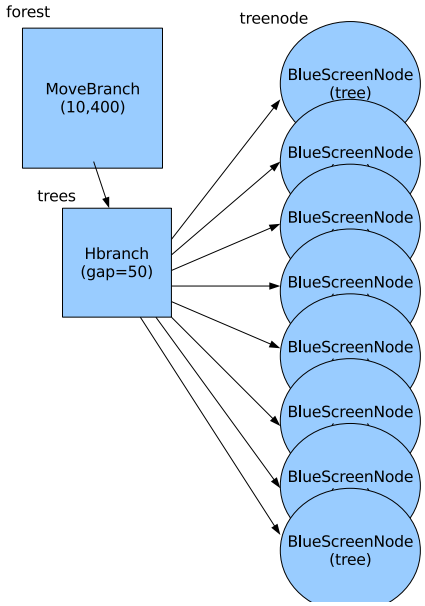

Figure 9.9: The forest branch created in setUp—arrows point to children

* * *

Common Bug: Declaring it hides the instance variable

By declaring the variable forest as a MoveBranch, we make forest a variable local to the method setUp. That means that the variable forest will not exist in renderAnimation. The variable wolfentry is not declared, so the reference in setUp is actually referencing the instance variable wolfentry. If we *had* declared wolfentry as a MoveBranch, the setUp would work still. However, renderAnimation would be referencing the wolfentry defined as an instance variable, which has no variable, and won't actually do anything. The wolves would never move. Declaring the variable in setUp makes it impossible to reach the instance variable with the same name.

The wolfentry branch is constructed much like the forest branch. There is a MoveBranch instance for positioning, then a VBranch for storing the wolves, then three BlueScreenNode instances for storing the actual wolves.

Program Example #68

Example Java Code: **Rest of setUp for WolfAttackMovie**

```
    // Make the cluster of retreating "wolves"
    wolfretreat = new MoveBranch(400,50); // starting position
    wolves = new VBranch(20); // space them out by 20 pixels between
    wolf1 = new BlueScreenNode(wolf.scale(0.5).flip());
    wolf2 = new BlueScreenNode(wolf.scale(0.5).flip());
    wolf3 = new BlueScreenNode(wolf.scale(0.5).flip());
    wolves.addChild(wolf1);wolves.addChild(wolf2);wolves.addChild(wolf3);
    wolfretreat.addChild(wolves);

    // Make the village
    MoveBranch village = new MoveBranch(300,450); // Village on bottom
    HBranch hhouses = new HBranch(40); // Houses are 40 pixels apart across
    BlueScreenNode house1 = new BlueScreenNode(house.scale(0.25));
    BlueScreenNode house2 = new BlueScreenNode(house.scale(0.25));
    BlueScreenNode house3 = new BlueScreenNode(house.scale(0.25));
    VBranch vhouses = new VBranch(-50); // Houses move UP, 50 pixels apart
    BlueScreenNode house4 = new BlueScreenNode(house.scale(0.25));
    BlueScreenNode house5 = new BlueScreenNode(house.scale(0.25));
    BlueScreenNode house6 = new BlueScreenNode(house.scale(0.25));
    vhouses.addChild(house4); vhouses.addChild(house5); vhouses.addChild(house6);
    hhouses.addChild(house1); hhouses.addChild(house2); hhouses.addChild(house3);
    hhouses.addChild(vhouses); // Yes, a VBranch can be a child of an HBranch!
    village.addChild(hhouses);

    // Make the monster
    hero = new MoveBranch(400,300);
    BlueScreenNode heronode = new BlueScreenNode(monster.scale(0.75).flip());
    hero.addChild(heronode);

    //Assemble the base scene
    sceneRoot = new Branch();
    sceneRoot.addChild(forest);
    sceneRoot.addChild(village);
    sceneRoot.addChild(wolfentry);
  }
```

How it works: The rest of setUp works similarly. We create a branch for wolfretreat, which is amazingly similar to wolfentry except that the wolves are flipped—they face away from the village. The village is a bit more complicated. There is an HBranch that contains three BlueScreenNode houses *and* a VBranch (with three more houses) as children. When the village is rendered, it will draw one house, then another, then the third, and then, at the spot where a fourth house would go, there is a vertical line of three more houses going straight up.

At the very end of setUp, we add into the sceneRoot the three branches that appear in the first scene: the forest, the village, and the wolfentry. Where is the wolfretreat and the hero branches? They are not in the initial

scene. They appear later, when we render the whole thing.

Program Example #69

Example Java Code: **Rendering just the first scene in WolfAttackMovie**

```
/**
 * Render just the first scene
 **/
public void renderScene() {
  Picture bg = new Picture(500,500);
  sceneRoot.drawOn(bg);
  bg.show();
}
```

When developing a movie, it's important to see if the basic setUp worked. When we were creating this first movie, we would often create a WolfAttackMovie instance, set it up, then renderScene to see how the first scene looked. We would then adjust positions of the forest and the village, and repeat until we were happy with the basic set up.

Now that we have our basic scene graph created, we can render our movie.

Program Example #70

Example Java Code: **renderAnimation in WolfAttackMovie**

```
/**
 * Render the whole animation
 **/
public void renderAnimation() {
  frames = new FrameSequence("C:/Temp/");
  frames.show();
  Picture bg;

  // First, the nasty wolvies come closer to the poor village
  // Cue the scary music
  for (int i=0; i<25; i++)
  {
    // Render the frame
    bg = new Picture(500,500);
    sceneRoot.drawOn(bg);
    frames.addFrame(bg);

    // Tweak the data structure
    wolfentry.moveTo(wolfentry.getXPos()+5,wolfentry.getYPos()+10);
  }
```

```
    // Now, our hero arrives!
    this.root().addChild(hero);
    // Render the frame
    bg = new Picture(500,500);
    sceneRoot.drawOn(bg);
    frames.addFrame(bg);

    // Remove the wolves entering, and insert the wolves retreating
    this.root().children.remove(wolfentry);
    this.root().addChild(wolfretreat);
    // Make sure that they retreat from the same place that they were at
    wolfretreat.moveTo(wolfentry.getXPos(),wolfentry.getYPos());
    // Render the frame
    bg = new Picture(500,500);
    sceneRoot.drawOn(bg);
    frames.addFrame(bg);

    // Now, the cowardly wolves hightail it out of there!
    // Cue the triumphant music
    for (int i=0; i<10; i++)
    {
      // Render the frame
      bg = new Picture(500,500);
      sceneRoot.drawOn(bg);
      frames.addFrame(bg);

      // Tweak the data structure
      wolfretreat.moveTo(wolfretreat.getXPos()-10,wolfretreat.getYPos()-20);
    }
  }
```

How it works: Rendering a frame from the scene graph is basically these three lines:

```
    // Render the frame
    bg = new Picture(500,500);
    sceneRoot.drawOn(bg);
    frames.addFrame(bg);
```

The rest of renderAnimation is changing the scene graph around this rendering.

- During the first 25 frames, the evil wolves are sneaking up on the poor, unsuspecting village. Between each frame, the wolves are moved by changing the position of the wolventry branch, with a horizontal (x) velocity of 5 pixels per frame and a vertical velocity of 10 pixels per frame.

```
wolfentry.moveTo(wolfentry.getXPos()+5,wolfentry.getYPos()+10);
```

- And then, the hero arrives! We insert the hero branch into the code and render.
- Now, we remove the wolfentry branch and insert the wolfretreat branch. We carefully make sure that the wolves are retreating from where they last stopped entering, with the line:

```
// Make sure that they retreat from the same place that they were at
wolfretreat.moveTo(wolfentry.getXPos(),wolfentry.getYPos());
```

- The wolves then scamper away, at a faster rate than when they entered.

We run the movie like this:

```
 Welcome to DrJava.
> WolfAttackMovie wam = new WolfAttackMovie(); wam.setUp(); wam.renderScene();
> wam.renderAnimation();
There are no frames to show yet.  When you add a frame it will be shown
> wam.replay();
```

Common Bug: When you run out of memory, within DrJava

Rendering large movies can easily eat up all available memory. You can make DrJava give your Interactions Pane more memory to execute, which would allow you to run large movie code from within DrJava. You can insert the options –Xms128m –Xmx512m in the PREFERENCES (under the EDIT menu) to take effect for *all* uses of the Interactions Pane (Figure 9.10).

Common Bug: Increasing memory at the command line

If you are not running DrJava, or you are so tight on memory that you don't even want DrJava in memory, you still have options if you are running out of memory. You can run your movies from the command line and specify the amount of memory you need.

First, you have to be able to run Java from the command line, which means being able to use the java and javac (*Java compiler*) commands. We have found that some Java installations do not have these set up right. Make sure that your Java JDK bin directory is in your class PATH. For Windows, you use the SYSTEM control panel to change environment variables. To use javac to compile your programs, you may need to change the CLASSPATH in System environment variables to point to your JAVA-SOURCE directory. If you have javac set up right, you should be able to

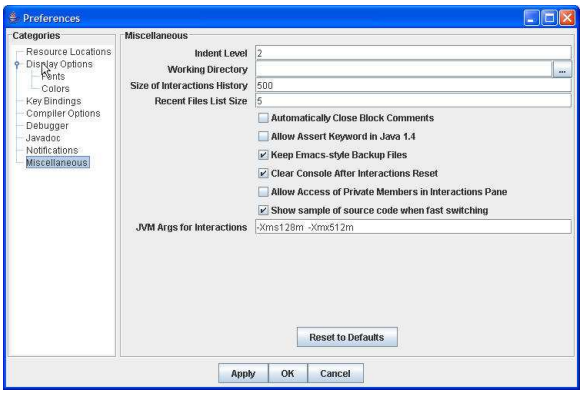

Figure 9.10: Reserving more memory for the Interactions Pane in DrJava's Preferences pane

compile your class files from outside of DrJava—at a command prompt, type javac (YourMovieClassNameHere).java.

To run it, type java −Xms128m −Xmx512m (YourMovieClassNameHere) −Xms128m says, "At the very least, give this program 128 megabytes to run." −Xmx512m says, "And give it up to 512 megabytes."

Now, when you run java like this, you're actually executing the **public static void** main method. Here's what we added to WolfAttackMovie to make it work from the command line:

```
public static void main(String[] args){
  WolfAttackMovie wam = new WolfAttackMovie();
  wam.setUp();
  wam.renderAnimation();
  wam.replay();
}
```

9.5 Implementing the Scene Graph

Recall lesson from the last chapter, that the way we *think* about a data structure does not have to match the way that it is implemented. While it is useful to think about branches having several children, we do not have to implement multiple references between (say) the forest branch and the tree nodes. Branches must have a way of adding and getting children—that's part of the definition of a tree. How it's implemented is up to us.

Our scene graphs are actually implemented as *lists of lists*. All siblings are connected through next links. Each branch is connected to its *first* child, and only the first child, through its children link. The class

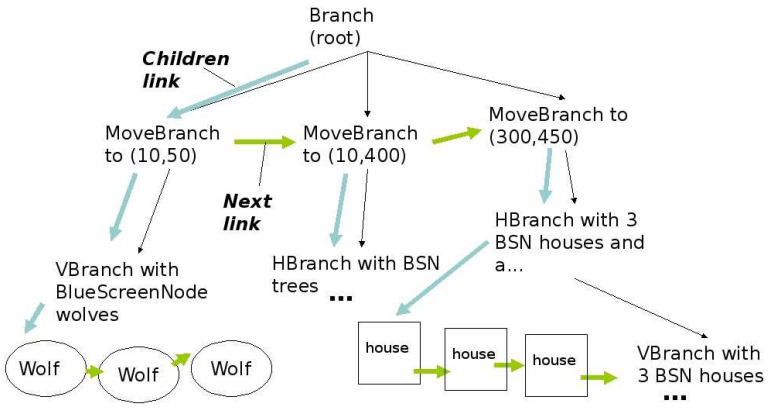

Figure 9.11: The implementation of the scene graph overlaid on the tree abstraction

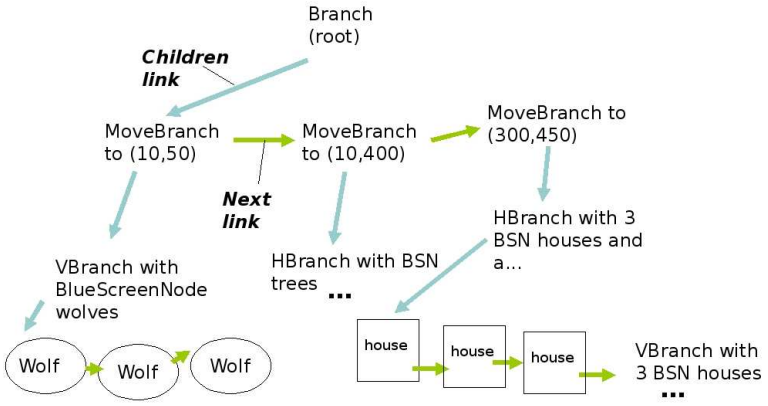

Figure 9.12: The actual implementation of the scene graph

Branch defines children, so all branches have the children link by inheritance. Figure 9.11 shows the abstraction of the scene graph tree (as seen in Figure 9.7), overlaid with the actual implementation.

We can think of our notion of parent nodes with children nodes as an abstraction. It is a useful way of thinking about trees. There are many ways of implementing that abstraction, though. Figure 9.12 shows the actual implementation of our scene graph.

The advantage of a list-of-lists implementation is that we are introducing no new data structure implementation ideas. It's all linked lists. There is one *special* kind of link, the children, both other than that, it's all next links and the same methods we've used all along.

* * *

Common Bug: Can't remove the first child

There is a bug in our implementation of linked lists up to this point in the book, and that same bug extends to our implementation of children in branches. We cannot remove the first item in a list. We will fix this bug in a few chapters, but for now, it dictates the order in which we add children to a branch. Notice that we add the forest as a child of the sceneRoot first. In general, forests don't move (Macbeth excepted) and don't disappear (rain forests excepted). Therefore, we won't have to remove the forest branch to the root, so it's safe to add first. If we would have added wolfentry as the first child of the sceneRoot, we would never have been able to remove it.

Implementing the abstract superclass for the scene graph: DrawableNode

The heart of our scene graph (literally, the base of the class hierarchy for these classes) is DrawableNode. It's actually not complicated at all. It's mostly the same as SceneElement or any of the other linked lists we've seen so-far.

Example Java Code: **DrawableNode** *Program Example #71*

```
/**
 * Stuff that all nodes and branches in the
 * scene tree know.
 **/
abstract public class DrawableNode {
  /**
   * The next branch/node/whatever to process
   **/
  public DrawableNode next;

  /**
   * Constructor for DrawableNode just sets
   * next to null
   **/
  public DrawableNode(){
    next = null;
  }

  /**
   * Methods to set and get next elements
   * @param nextOne next element in list
```

```
 **/
public void setNext(DrawableNode nextOne){
  this.next = nextOne;
}

public DrawableNode getNext(){
  return this.next;
}

/**
 * Use the given turtle to draw oneself
 * @param t the Turtle to draw with
 **/
abstract public void drawWith(Turtle t);
// No body in the superclass

/**
 * Draw on the given picture
 **/
public void drawOn(Picture bg){
  Turtle t = new Turtle(bg);
  t.setPenDown(false);
  this.drawWith(t);
}

/** Method to remove node from list, fixing links appropriately.
 * @param node element to remove from list.
 **/
public void remove(DrawableNode node){
  if (node==this)
  {
    System.out.println("I can't remove the first node from the list.");
    return;
  };

  DrawableNode current = this;
  // While there are more nodes to consider
  while (current.getNext() != null)
  {
    if (current.getNext() == node){
      // Simply make node's next be this next
      current.setNext(node.getNext());
      // Make this node point to nothing
      node.setNext(null);
      return;
    }
    current = current.getNext();
  }
}
```

```
  /**
   * Insert the input node after this node.
   * @param node element to insert after this.
   **/
  public void insertAfter(DrawableNode node){
    // Save what "this" currently points at
    DrawableNode oldNext = this.getNext();
    this.setNext(node);
    node.setNext(oldNext);
  }

  /**
   * Return the last element in the list
   **/
    public DrawableNode last() {
      DrawableNode current;

      current = this;
      while (current.getNext() != null)
      {
        current = current.getNext();
      };
      return current;
  }

  /**
   * Add the input node after the last node in this list.
   * @param node element to insert after this.
   **/
  public void add(DrawableNode node){
    this.last().insertAfter(node);
  }

}
```

How it works: Class DrawableNode has two main functions.

- The first is to be an abstract superclass for defining linked lists. For that reason, it has a next variable, operations for getting and setting next, and list operations like add and remove.

- The second is to be "drawable." Every DrawableNode subclass instance must know how to drawOn and drawWith.

Implementing the leaf nodes: PictNode and BlueScreenNode

Leaf nodes in the scene graphs are the pictures themselves. In WolfAttackMovie, these are the trees, houses, wolves, and hero. The class PictNode simply drops pictures—we don't actually use it in WolfAttackMovie. It is the superclass for BlueScreenNode, the leaf node class that we use in the example movie.

Program Example #72

Example Java Code: **PictNode**

```
/*
 * PictNode is a class representing a drawn picture
 * node in a scene tree.
 **/
public class PictNode extends DrawableNode {
  /**
   * The picture I'm associated with
   **/
  Picture myPict;

  /*
   * Make me with this picture
   * @param pict the Picture I'm associated with
   **/
  public PictNode(Picture pict){
    super(); // Call superclass constructor
    myPict = pict;
  }

  /**
   * Method to return a string with informaiton
   * about this node
   */
  public String toString()
  {
    return "PictNode (with picture: "+myPict+" and next: "+next;
  }

  /*
   * Use the given turtle to draw oneself
   * @param pen the Turtle to draw with
   **/
  public void drawWith(Turtle pen){
    pen.drop(myPict);
  }
}
```

Figure 9.13: How we actually got some of the bluescreen pictures in this book, such as our hero in WolfAttackMovie

How it works: Class PictNode is really quite simple. It has an instance variable, myPict that represents the picture to be shown for the node. The heart of the class is the drawWith method which only asks the input turtle to drop the picture.

The class BlueScreenNode inherits from PictNode and is only slightly more complicated. Instead of dropping the picture, it uses chromakey to remove the blue background for the image. (Figure 9.13 shows how that blue background got there in the first place.)

Example Java Code: **BlueScreenNode**

Program Example #73

```
/*
 * BlueScreenNode is a PictNode that composes the
 * picture using the bluescreen() method in Picture
 **/
public class BlueScreenNode extends PictNode {

  /*
   * Construct does nothing fancy
   **/
  public BlueScreenNode(Picture p){
    super(p); // Call superclass constructor
  }
```

```
  /**
   * Method to return a string with informaiton
   * about this node
   */
  public String toString()
  {
    return "BlueScreenNode (with picture: "+myPict+" and next: "+next;
  }

  /*
   * Use the given turtle to draw oneself
   * Get the turtle's picture, then bluescreen onto it
   * @param pen the Turtle to draw with
   **/
  public void drawWith(Turtle pen){
    Picture bg = pen.getPicture();
    myPict.bluescreen(bg,pen.getXPos(),pen.getYPos());
  }
}
```

How it works: The method drawWith in BlueScreenNode is a little tricky. It asks the turtle that comes in as input "What's your picture?", e.g., Picture bg = pen.getPicture();. It then calls the Picture method bluescreen to draw the picture, on the background from the turtle, at the *turtle's* x, y, i.e., myPict.bluescreen(bg,pen.getXPos(),pen.getYPos());.

An interesting side comment to make here is that both of these classes know how to toString, that is, return a string representation of themselves. Each simply returns the printable representation of its string and its next. For a brand new node, the next is simply **null**.

```
> BlueScreenNode bsn = new BlueScreenNode(
new Picture(FileChooser.pickAFile()))
> bsn
BlueScreenNode (with picture: Picture, filename /home/guzdial/cs1316/MediaSources/St
height 333 width 199 and next: null
```

Implementing the branches: Branch, MoveBranch, VBranch, and HBranch

The branch classes (the class Branch and its subclasses) have children links. Because they inherit from DrawableNode, they also have next links. Thus, branch instances link to both children and siblings—that's what makes them into branches of trees.

Notice that the type of the children link is DrawableNode. That means that *any* other kind of node can be a child of any branch—either leaf nodes or other other branches. Thus, a tree can be of any *depth* (the maximum number of nodes visited to get from the root to a leaf node) or complexity.

* * *

Example Java Code: **Branch**

Program Example #74

```
public class Branch extends DrawableNode {
  /*
   * A list of children to draw
   */
  public DrawableNode children;

  /*
   * Construct a branch with children and
   * next as null
   **/
  public Branch(){
    super(); // Call superclass constructor
    children = null;
  }

  /**
   * Method to return a string with informaiton
   * about this branch
   */
  public String toString()
  {
    String childString = "No children", nextString="No next";
    if (children != null)
    {childString = children.toString();}
    if (next != null)
    {nextString = next.toString();}

    return "Branch (with child: "+childString+" and next: "+
      nextString+")";
  }

  /**
   * Method to add nodes to children
   **/
  public void addChild(DrawableNode child){
    if (children != null)
    {children.add(child);}
      else
      {children = child;}
  }

  /*
   * Ask all our children to draw,
   * then let next draw.
   * @param pen Turtle to draw with
```

```
   **/
  public void drawWith(Turtle pen){
    DrawableNode current = children;

    // Tell the children to draw
    while (current != null){
      current.drawWith(pen);
      current = current.getNext();
    }

    // Tell my next to draw
    if (this.getNext() != null)
    {current = this.getNext();
      current.drawWith(pen);
    }
  }
}
```

How it works: The most important responsibility of branches is to manage their children. Instances of Branch (and its subclasses) know their children reference. A branch adds a child (addChild) by first seeing if children is null—if it is, then the new addition is what children is set to; if it is not, then we add the new addition to the children list.

Branches also know how to drawWith. The definition of drawWith says:

- First, ask all my children to draw.

```
DrawableNode current = children;

// Tell the children to draw
while (current != null){
  current.drawWith(pen);
  current = current.getNext();
}
```

- Then, tell my next that it can draw.

```
// Tell my next to draw
if (this.getNext() != null)
{current = this.getNext();
  current.drawWith(pen);
}
```

There is a similar algorithm going on in the definition of toString, to convert a branch to a printable representation. The algorithm is to collect all the string representations of the children, then of the next, and then return all those pieces.

This means that we can actually watch the construction of a branch, by printing it at each step. Below we see a BlueScreenNode, Branch, and

PictNode created and connected. The BlueScreenNode shows up first, and when we add the PictNode, it appears as the next of the BlueScreenNode.

```
> BlueScreenNode bsn = new BlueScreenNode(new Picture(FileChooser.pickAFile()))
> bsn
BlueScreenNode (with picture: Picture, filename /home/guzdial/cs1316/MediaSources/Student10.jp
height 333 width 199 and next: null
> Branch b = new Branch()
> b.addChild(bsn)
> b
Branch (with child: BlueScreenNode (with picture:
Picture, filename /home/guzdial/cs1316/MediaSources/student1.jpg
height 369 width 213 and next: null and next: No next)
> PictNode pn = new PictNode(new Picture(FileChooser.pickAFile()))
> b.addChild(pn)
> b
Branch (with child: BlueScreenNode (with picture:
Picture, filename /home/guzdial/cs1316/MediaSources/student1.jpg
height 369 width 213 and next: PictNode (with picture:
Picture, filename /home/guzdial/cs1316/MediaSources/Student7.jpg
height 422 width 419 and next: null and next: No next)
```

The two branch subclasses that position their children automatically, HBranch and VBranch, only provide two methods: a constructor for storing the gap between children, and a new drawWith which moves the turtle appropriately between drawings of children.

Example Java Code: **HBranch**

Program Example #75

```
public class HBranch extends Branch {

  /**
   * Horizontal gap between children
   **/
  int gap;

  /*
   * Construct a branch with children and
   * next as null
   **/
  public HBranch(int spacing){
    super(); // Call superclass constructor
    gap = spacing;
  }

  /**
   * Method to return a string with information
   * about this branch
```

```
   */
  public String toString()
  {
    return "Horizontal "+super.toString();
  }

  /*
   * Ask all our children to draw,
   * then let next draw.
   * @param pen Turtle to draw with
   **/
  public void drawWith(Turtle pen){
    DrawableNode current = children;

    // Have my children draw
    while (current != null){
      current.drawWith(pen);
      pen.moveTo(pen.getXPos()+gap,pen.getYPos());
      current = current.getNext();
    }

    // Have my next draw
    if (this.getNext() != null)
    {current = this.getNext();
      current.drawWith(pen);}
  }
}
```

Program Example #76

Example Java Code: **VBranch**

```
public class VBranch extends Branch {

  /**
   * Vertical gap between children
   **/
  int gap;

  /*
   * Construct a branch with children and
   * next as null
   **/
  public VBranch(int spacing){
    super(); // Call superclass constructor
    gap = spacing;
  }
```

```
  /**
   * Method to return a string with informaiton
   * about this branch
   */
  public String toString()
  {
    return "Vertical "+super.toString();
  }

  /*
   * Ask all our children to draw,
   * then let next draw.
   * @param pen Turtle to draw with
   **/
  public void drawWith(Turtle pen){
    DrawableNode current = children;

    // Have my children draw
    while (current != null){
      current.drawWith(pen);
      pen.moveTo(pen.getXPos(),pen.getYPos()+gap);
      current =current.getNext();
    }

    // Have my next draw
    if (this.getNext() != null)
    {current = this.getNext();
      current.drawWith(pen);}
  }
}
```

The class MoveBranch differs in that it keeps track of an x, y position

Example Java Code: **MoveBranch**

Program Example #77

```
public class MoveBranch extends Branch {

  /**
   * Position where to draw at
   **/
  int x,y;

  /**
   * Construct a branch with children and
   * next as null
```

```
   **/
  public MoveBranch(int x, int y){
    super(); // Call superclass constructor
    this.x = x;
    this.y = y;
  }

  /**
   * Accessors
   **/
  public int getXPos() {return this.x;}
  public int getYPos() {return this.y;}
  public void moveTo(int x, int y){
    this.x = x; this.y = y;}

  /**
   * Method to return a string with informaiton
   * about this branch
   */
  public String toString()
  {
    return "Move ("+x+","+y+") "+super.toString();
  }

  /*
   * Set the location, then draw
   * @param pen Turtle to draw with
   **/
  public void drawWith(Turtle pen){
    pen.moveTo(this.x,this.y);
    super.drawWith(pen); // Do a normal branch now
  }
}
```

What would happen if we decided that the moveTo of the pen in MoveBranch's drawWith should occur *after* processing the children and before processing the next? What would happen if all the branches processed the next before the children? These aren't unreasonable possibilities. They describe different kinds of *traversals* that one can make of the data structure.

The Line between Structure and Behavior

Here's a thought experiment: Where is the *program* in our scene graph?

- Is the program the class DrawableNode and its subclasses? That can't be it—by themselves, they don't do anything at all. The DrawableNode class hierarchy defines the *behavior*, but not how that behavior is structured and executed.

- Is the program in the class WolfAttackMovie? It is true that WolfAttackMovie assembles all the pieces from the DrawableNode classes in order to define the movie. The class WolfAttackMovie defines the *structure* of the movie from those classes.
- However, the actual scenes are not defined in WolfAttackMovie. Instead, the scenes emerge from executing that movie. The actual layout of the trees and village houses is not specified in WolfAttackMovie. Instead, it's determined by the branches in the tree when the tree is rendered. The actual data structure and its use blends structure and behavior.

9.6 Exercises

Ex. 10 — Implement one different traversal of the scene graph, as described at the end of the branch subsection above. Does it make a difference in how the scene looks?

Ex. 11 — Most of renderAnimation in WolfAttackMovie is about changing the location of MoveBranch instances. Create a new class RelativeMoveBranch which is created with a *starting location* (x, y) and a *horizontal velocity* and *vertical velocity*. Each time that an instance of a RelativeMoveBranch is told to update, it automatically updates its current location by its velocity. Rewrite WolfAttackMovie to use this new kind of branch.

Ex. 12 — Both PictNode and BlueScreenNode presume that a character is represented by a single image, just a single picture, e.g., if our wolves moved, changed position of their head and paws, or even appeared to walk. The animation would be improved considerably if the characters changed. Create a new class, CharacterNode that maintains a list of pictures (your choice if the implementation is an array, vector, or linked list of pictures) for a given character. Each time an instance of CharacterNode is asked to drawWith, the current character image is incremented (perhaps randomly among the list of pictures), so that the next rendering draws a different image for the character.

Ex. 13 — Create an animation of *at least* 20 frames with sounds associated with frames.
Here's how you need to do it:

- Create a tree of images that describe your scene. I'll refer to this as the scene structure.
- Create another list with the sounds to be played during the animation of this tree. (Sounds could be a rest!)

- Here's the key part! When you animate your scene (for at least 20 scenes!) and play your sounds, YOU CANNOT MAKE ANY NEW SOUNDS! You must play your sounds out of your list of sounds. In other words, the sounds must be pre-made and assembled in a structure before you start your animation.

You can use and modify any of the data structures that we've described in class. You can create new data structures if you'd like.
You will also need to create a class (call it AnimationRunner). We should be able to use it by creating an instance of the class
(AnimationRunner ar = **new** AnimationRunner()),
and then...

- The method setUp() sent to the instance (ar.setUp()) should set up the two data structures.
- The method play() send to the instance should play the movie with sound.
- The method replay() should replay the FrameSequence, but won't do the sound, too.

There are *several* ways to handle the animation.Here's one:

- Render the first frame to a FrameSequence instance.
- For each frame that you want to generate (There must be at least 20 frames):
  - –Make a change in the scene structure. Any change you want is acceptable.
  - –Render the scene structure.
  - –Play the sound in the frame list element. Use blockingPlay() instead of play() on your sound to make the processing wait (synchronize) until the sound is done before moving on. (Hint: If your sound is over 1/10 of a second long, you can't get 10 frames per second! These will be short sounds! Want something to play over two frames? Play the first half in one frame, and the second half in the next frame.) Note: You don't *have* to use blockingPlay(). You can use a mixture of play() and blockingPlay() to get better response while still maintaining synchrony.

10 Lists and Trees for Structuring Sounds

Chapter Learning Objectives

In the past chapters, we used linked lists and trees to structure images and music. In this chapter, we'll add a new medium to our repertoire for dynamic data structures, sampled sounds (e.g., `.WAV` files). But we'll use *recursion* for the traversals, which provides us a more compact way of describing our traversals.

The computer science goals for this chapter are:

- To iterate across linked lists and trees using recursion.
- To replace elements in a data structure, and to define what the "same" node means.
- To explore different kinds of traversals. We will take an operation embedded in a branch, and choose to apply it to the next branch or to the children branch.

The media learning goals for this chapter are:

- To use our new, dynamic ways of structuring media to describe sound patterns and music.

10.1 Composing with Sampled Sounds and Linked Lists: Recursive Traversals

We originally started down this path of linked lists and trees in order to create a way of composing music flexibly. Our original efforts was with MIDI. However, one might also want to compose sound using sampled or recorded sound. In this chapter, we use the same data structures that we have developed in the previous few chapters in the service of supporting flexible composition of sampled sounds in linked lists.

It's pretty straight forward for us to define a simple linked list structure now. The below definition of a linked list node, SoundElement, that has a Sound instance within it has little new for us.

* * *

Program Example #78

Example Java Code: **SoundElement**

```
/**
 * Sounds for a linked list
 **/
public class SoundElement {

  /**
   * The sound this element is associated with
   **/
  Sound mySound;

  /**
   * The next element to process
   **/
  public SoundElement next;

  /**
   * Constructor sets next to null
   * and references the input sound.
   **/
  public SoundElement(Sound aSound){
    next = null;
    mySound = aSound;
  }

  /**
   * Return my sound
   **/
  public Sound getSound(){return mySound;}

  /**
   * Play JUST me, blocked.
   **/
  public void playSound(){mySound.blockingPlay();}
  public void blockingPlay(){mySound.blockingPlay();}

  /**
   * Provide a printable representation of me
   **/
  public String toString(){
    return "SoundElement with sound: "+mySound+" (and next: "+next+").";
  }

  /**
   * Methods to set and get next elements
```

```
   * @param nextOne next element in list
   **/
  public void setNext(SoundElement nextOne){
    this.next = nextOne;
  }

  public SoundElement getNext(){
    return this.next;
  }

  /**
   * Play the list of sound elements
   * after me
   **/
  public void playFromMeOn(){
    this.collect().play();
  }

  /**
   * Collect all the sounds from me on,
   * recursively.
   **/
  public Sound collect(){
    if (this.getNext() == null)
    {return mySound;}
    else
    {return mySound.append(this.getNext().collect());}
  }

  /** Method to remove node from list, fixing links appropriately.
   * @param node element to remove from list.
   **/
  public void remove(SoundElement node){
    if (node==this)
    {
      System.out.println("I can't remove the first node from the list.");
      return;
    };

    SoundElement current = this;
    // While there are more nodes to consider
    while (current.getNext() != null)
    {
      if (current.getNext() == node){
        // Simply make node's next be this next
        current.setNext(node.getNext());
        // Make this node point to nothing
        node.setNext(null);
        return;
      }
```

```
      current = current.getNext();
    }
  }

  /**
   * Insert the input node after this node.
   * @param node element to insert after this.
   **/
  public void insertAfter(SoundElement node){
    // Save what "this" currently points at
    SoundElement oldNext = this.getNext();
    this.setNext(node);
    node.setNext(oldNext);
  }

  /**
   * Return the last element in the list
   **/
    public SoundElement last() {
      SoundElement current;

      current = this;
      while (current.getNext() != null)
      {
        current = current.getNext();
      };
      return current;
  }

  /**
   * Add the input node after the last node in this list.
   * @param node element to insert after this.
   **/
  public void add(SoundElement node){
    this.last().insertAfter(node);
  }
```

How it works: There are two interesting elements in this linked list implementation. Both of them involve the use of *recursion* for traversing a data structure.

Look at how we define toString for SoundElement.

```
return "SoundElement with sound: "+mySound+" (and next: "+next+").";
```

That's really straightforward, isn't it? Display "SoundElement with...", then the printable representation of the sound, and then the printable representation of the next. When the next is just **null**, that makes perfect

sense how it would work.

```
> Sound s = new Sound("D:/cs1316/mediasources/shh-a-h.wav");
> Sound t = new Sound("D:/cs1316/mediasources/croak-h.wav");
> Sound u = new Sound("D:/cs1316/mediasources/clap-q.wav");
> SoundElement e1 = new SoundElement(s);
> SoundElement e2 = new SoundElement(t);
> SoundElement e3 = new SoundElement(u);
> e1.playFromMeOn();
> e1
SoundElement with sound: Sound file:
D:/cs1316/mediasources/shh-a-h.wav
number of samples: 11004 (and next: null).
```

That makes sense. The interesting thing is that this works, still, when we have additional SoundElement instances in it.

```
> e1.setNext(e2)
> e1
SoundElement with sound:
Sound file: D:/cs1316/mediasources/shh-a-h.wav
number of samples: 11004 (and next:
SoundElement with sound: Sound file:
D:/cs1316/mediasources/croak-h.wav
number of samples: 8808 (and next: null).).
> e2.setNext(e3)
> e1
SoundElement with sound: Sound file: D:/cs1316/mediasources/shh-a-h.wav
number of samples: 11004 (and next:
SoundElement with sound:
Sound file: D:/cs1316/mediasources/croak-h.wav
number of samples: 8808 (and next:
SoundElement with sound:
Sound file: D:/cs1316/mediasources/clap-q.wav
number of samples: 4584 (and next: null).).).
```

Where did all that text come from? When we try to print next and it is *not* **null**, then the object that next refers to is asked to convert itself to a string (toString). If that next object is also a SoundElement (as in the above examples), then the *same* toString method is executed (the one in SceneElement). The difference in the next call is that the object being asked to convert itsef (**this**) is different.

In the above example, e1 starts executing toString, which then tries to print next—which is e2. The node e2 is then asked toString, and when it gets to next, the node e3 is asked to convert itself toString. When e3 is done (since it's next is **null**), e3.toString() ends, then e2.toString() ends, and finally the original call to print e1 ends. This process is called a *recursive traversal* of the linked list—we are *traversing* (walking along, visiting) each node of the linked list, by using the same method which repeatedly calls itself. In

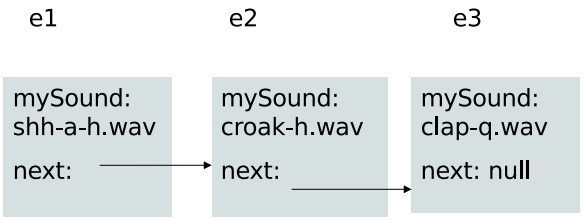

Figure 10.1: The initial SoundElement list

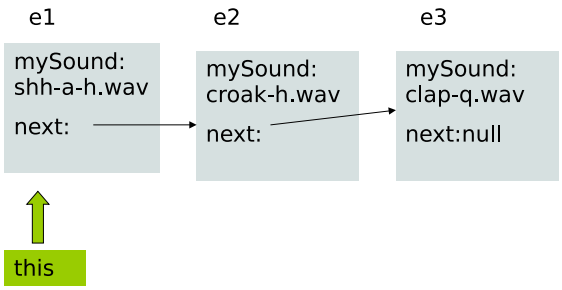

Figure 10.2: As we start executing playFromMeOn()

the case of toString, the calls are implicit—they happen when we try to print out next.

Tracing a Recursive Traversal

In the above example, if we then asked e1.playFromMeOn(), another recursive traversal would occur. Let's trace what happens. When we start the execution, the linked list looks like Figure 10.1.

The method playFromMeOn() is really short—it only says **this**.collect().play();. The method collect() does all the hard work. It collects the sounds from all the individual nodes into one big Sound instance, so that the big sound can finally be played. So, the interest work occurs in collect().

So we start out by asking e1 (Figure 10.2), to execute the below code.

```
public Sound collect(){
  if (this.getNext() == null)
  {return mySound;}
```

Clearly, getNext() is not **null**, so we end up making the recursive call.

```
else
  {return mySound.append(this.getNext().collect());}
```

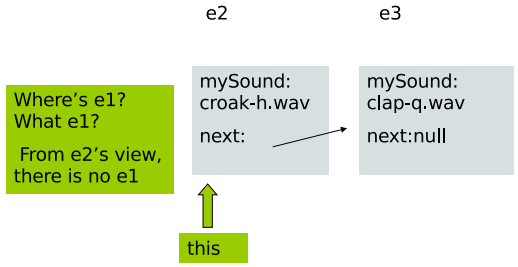

Figure 10.3: Calling e2.collect()

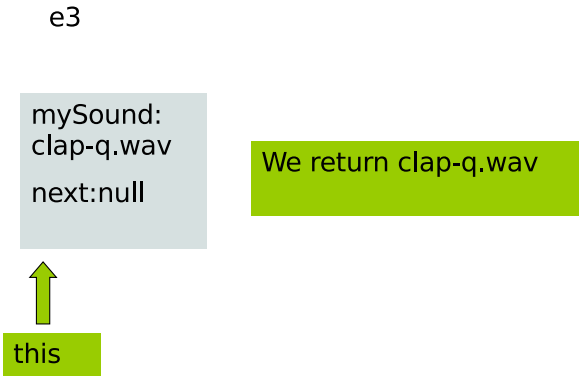

Figure 10.4: Finally, we can return a sound

Our call to e1.collect() is now *frozen*. It's not ended, but it can't go any further yet. It now has to process **this**.getNext().collect().

We are now asking e2 (which is what **this**.getNext() means) to collect() (Figure 10.3). The question of "Where is e1?" isn't relevant. From e2's perspective, e1 doesn't exist. We're simply asking e2.collect().

The node e2 also has a next, so we execute **else return** mySound.append(**this**.getNext().collect());. Now, we have the execution of e2.collect() *frozen*. Neither e1.collect() nor e2.collect() can end yet—they're waiting in limbo.

Now, we execute e3.collect() (Figure 10.4). Finally the first part of collect() is true—next is **null**. We return the sound in e3.

Now we can *unfreeze* e2.collect() (Figure 10.5). Now that we have **this**.getNext().collect(), we can append to it the sound of e2 and return back to e1.collect().

Finally, e1.collect() gets the sounds from e2 and e3 appended together, from its execution of **this**.getNext().collect(). The sound from e1 gets appended to the rest, and we finally return from e1.collect(). We return "shh-a-h.wav" appended with "croak-h.wav" appended with "clap-q.wav." That's

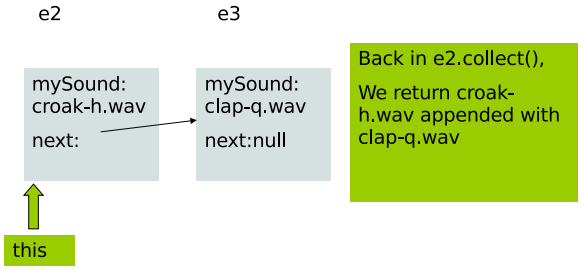

Figure 10.5: Ending e2.collect()

what finally gets played.

Making It Work Tip: Tracing your program

It is very important for you to be able to do what we just did in this section. You should be able to trace through your programs when you need to. You don't always have to be able to trace through your programs in this much detail, but when something goes wrong, it helps enormously to be able to do this.

Testing and Replacing

Below is a program that constructs a linked list from the SoundElement class.

Program Example #79

Example Java Code: **SoundListText: Constructing a SoundElement list**

```
public class SoundListTest {
  SoundElement root;

  public SoundElement root(){ return root;}

  public void setUp(){
   Sound s = new Sound(FileChooser.getMediaPath( "scratch-h.wav"));
    root = new SoundElement(s);

    s = new Sound(FileChooser.getMediaPath( "gonga-2.wav"));
    SoundElement one = new SoundElement(s);
    root.repeatNext(one,10);
```

```
    s = new Sound(FileChooser.getMediaPath( "scritch-q.wav"));
    SoundElement two = new SoundElement(s);
    root.weave(two,3,3);
    s = new Sound(FileChooser.getMediaPath( "clap-q.wav"));
    SoundElement three = new SoundElement(s);
    root.weave(three,5,2);

    root.playFromMeOn();
  }
```

Go ahead and try it. You'll notice that you get sounds between other sounds because of the use of repeatNext and weave for SoundElement. It looks much like the code that we developed back for MIDI.

Example Java Code: **RepeatNext for SoundElement** *Program Example #80*

```
/**
  * Repeat the input phrase for the number of times specified.
  * It always appends to the current node, NOT insert.
  * @param nextOne node to be copied in to list
  * @param count number of times to copy it in.
  */
 public void repeatNext(SoundElement nextOne,int count) {
   SoundElement current = this; // Start from here
   SoundElement copy; // Where we keep the current copy

   for (int i=1; i <= count; i++)
   {
     copy = nextOne.copyNode(); // Make a copy
     current.setNext(copy); // Set as next
     current = copy; // Now append to copy
   }
 }
```

Example Java Code: **Weave for SoundElement** *Program Example #81*

```
/**
  * Weave the input sound count times every skipAmount elements
  * @param nextOne SoundElement to be copied into the list
  * @param count how many times to copy
```

```
   * @param skipAmount how many nodes to skip per weave
   */
  public void weave(SoundElement nextOne, int count, int skipAmount)
  {
    SoundElement current = this; // Start from here
    SoundElement copy; // Where we keep the one to be weaved in
    SoundElement oldNext; // Need this to insert properly
    int skipped; // Number skipped currently

    for (int i=1; i <= count; i++)
    {
      copy = nextOne.copyNode(); // Make a copy

      //Skip skipAmount nodes
      skipped = 1;
      while ((current.getNext() != null) && (skipped < skipAmount))
      {
        current = current.getNext();
        skipped++;
      };

      oldNext = current.getNext(); // Save its next
      current.insertAfter(copy); // Insert the copy after this one
      current = oldNext; // Continue on with the rest
      if (current == null) // Did we actually get to the end early?
         break; // Leave the loop
    }
  }
```

In both of these methods, we create a *copy* of the input node, using the method copyNode. How does that work? What does it mean to copy a SoundElement node?

Program Example #82

Example Java Code: **copyNode for SoundElement**

```
  /**
   * copyNode returns a copy of this element
   * @return another element with the same sound
   */
  public SoundElement copyNode(){
    Sound copySound;
    if (this.mySound.getFileName() == null)
    {copySound = this.mySound.scale(1.0);} // Does nothing -- copies
    else
    {copySound = new Sound(this.mySound.getFileName());} // Copy from file
```

```
    SoundElement returnMe = new SoundElement(copySound);
    return returnMe;
  }
```

How it works: What does it mean for one node to be a *copy* of another node? The most critical thing is for the node to have the same sound. It turns out that Sound instances have more than just a bunch of samples associated with them—they also know their filename. Sometimes they do. If a Sound instance is not created from a file, perhaps created from manipulating some other sound (by scaling or appending, for example), then the sound has no filename associated with it.

So, if we want a SoundElement node to have an identical structure, all the way down to the structure of its Sound, then we have to deal with two cases: (a) if there is no filename, and (b) if there is. If there is a filename, then creating the right sound is easy—we simply go create a new sound from the same filename. If there is no filename, we need some way to get a copy of that sound. This method uses one way: scale by 1.0. Scaling by 1.0 is simply a copy of the original sound.

A Problem and Its Solution: Removing a node without recreating the list

You should try that example in SoundListTest. It's really annoying. There are 10 gongs in there that seemingly keep going on and on and on. How can we get rid of them?

The obvious thing to do is to modify the SoundListTest class to use fewer (or zero!) gongs, recompile, and re-run it. What if we couldn't? Imagine that you have a long linked list that has been created through many different operations, and it would take too long or be too hard to recreate it.

What we can do is to walk through the list, find the gongs, and replace the sounds in those nodes with some other sound. We'll call it "degonging."

Example Java Code: **De-gonging the list**

Program Example #83

```
public void degong(){
    Sound gong = new Sound(FileChooser.getMediaPath("gonga-2.wav"));
    Sound snap = new Sound(FileChooser.getMediaPath("snap-tenth.wav"));
    root.replace(gong,snap);
```

```
}
```

We know how to write replace. We're simply going to iterate through the list, find the nodes that have the gong, and replace it with the snap. However, it's not quite that easy. How do you know which sounds contain the gong sound? That's the trick. The gong sound in the SoundElement is *not* the same object as is input (e.g., it's not == to the sound gong above). We have to figure out what it means for two objects (the input sound and the sound in a node) to be *equivalent* even if they're not the exact same object.

Program Example #84

Example Java Code: **replace for SoundElement**

```
/**
  * Replace the one sound with the other sound
  * in all the elements from me on.
  * Decide two sounds are equal if come from same filename
  * @param oldSound sound to be replaced
  * @param newSOund sound to put in its place
  **/
 public void replace(Sound oldSound, Sound newSound){
   if (mySound.getFileName() != null)
   {if (mySound.getFileName().equals(oldSound.getFileName()))
     {mySound = newSound;}}

     if (next != null)
   {next.replace(oldSound,newSound);}
   }
```

How it works: For our purposes, we'll use a very simply notion of equivalence. If the sound in the node has the same fileName as the input sound, it's the same. Obviously, this is a poor approach, e.g., if you have created the sound that you're looking for, you won't possibly make it. It will work for our de-gonging method, though, since we want to find and remove sounds made from the "gong" file.

Notice that, since we're comparing two strings (the filenames), we use the equals method. We can't use == method because that checks if two objects are *equal*, the exact same object. It's not the case that the two strings are the same. We need to check if the two strings have the same characters—that's what the equals method does. We have to check first that there's a fileName string at all. If there isn't (e.g., the Sound instance was created via scale or some other method that returns a Sound instance

that was never associated with a file), then the fileName is **null**—and **null** does not understand equals.

The replace method has no explicit loop—no **for**, no **while**. Instead, it traverses the list using *recursion*. We call the method replace on each segment of the linked list that we want to check. Let's walk through how that works. Imagine that we execute e1.replace(croak,clap) on the list in Figure 10.6.

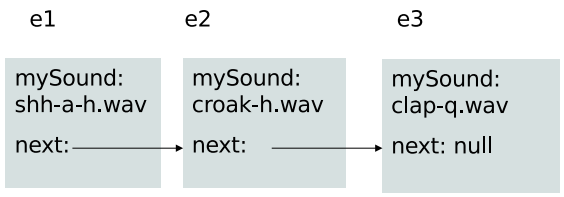

Figure 10.6: Starting out with e1.replace(croak,clap)

We start out executing the method replace in Figure 10.7:

```
public void replace(Sound oldSound, Sound newSound){
    if (mySound.getFileName() != null)
    {if (mySound.getFileName().equals(oldSound.getFileName()))
      {mySound = newSound;}}
```

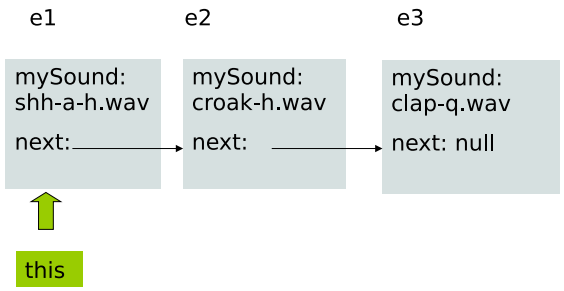

Figure 10.7: Checking the first node

It is clear that the "croak" sound is not the same as the "shh" sound, so we continue on.

```
if (next != null)
    {next.replace(oldSound,newSound);}
```

Now, e2 is asked to replace(croak,clap) (Figure 10.8). Node e2 *does* contain "croak" so we replace it with a "clap." Since the next of e2 is *not* **null**, we go on to call e3.replace(croak,clap).

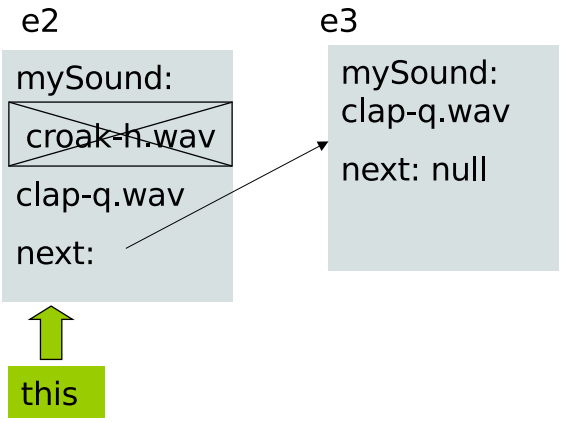

Figure 10.8: Replacing from e2 on

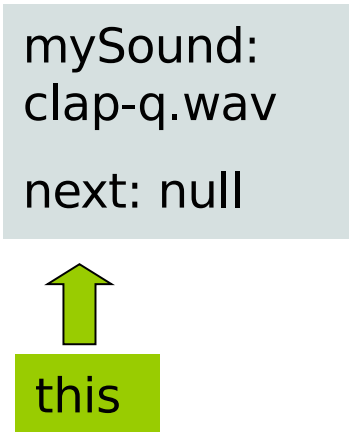

Figure 10.9: Finally, replace on node e3

The node e3 does not contain the "croak" sound, so we don't replace anything (Figure 10.9). The next value on e3 *is* **null**, so we return.

While it is invisible to us (no additional code is executed), after e3.replace(croak,clap) ends, the method execution for e2.replace(croak,clap) also ends. Finally, e1.replace(croak,clap) ends. Those other method executions were awaiting the completion of the later method executions—they could be thought of as being "frozen" or "in limbo."

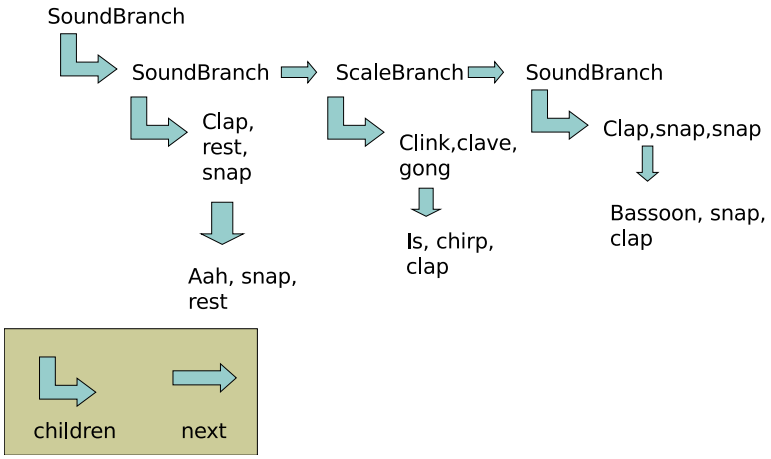

Figure 10.10: Our first sampled sound tree

10.2 Using Trees to Structure Sampled Sounds

Just as with MIDI phrases and images, we may want to structure our sampled sounds in compositions with a sense of clusters or hierarchy. A long, linear list of sampled sounds is hard to manipulate and think about. We naturally think about sound in clusters: motif expositions and recapitulations, or verses and chorus. So, just like with MIDI phrases and images, we can explore the use of trees to structure our sampled sounds.

Just like with our MIDI phrases and images, we might also embed operations in our branches. We might have branches that reverse the sound collected from the children (all appended together), or scale the children's sounds, or normalize the volume of the children's sound. Thus, we can created trees of sampled sounds that combine structure and behavior.

We are going to use an implementation of trees that is similar to the one that we created for images, the structure called a *linked list of lists*. All nodes will have a next, and branches will also have a children link (Figure 10.10). We will create a normal branch, and a ScaleBranch which changes the frequency of the sounds that are children of the branch.

We would create and play this example sound tree like this:

```
Welcome to DrJava.
> SoundTreeExample tree = new SoundTreeExample();
> tree.setUp();
> tree.play()
```

We might then change the scaling factor in our ScaleBranch, then replay the tree:

```
> tree.playScaled(2.0);
> tree.play();
```

Here's what our class SoundTreeExample looks like.

Program Example #85

Example Java Code: **SoundTreeExample**

```
public class SoundTreeExample {

  // Declared here because
  // needed between methods
  ScaleBranch scaledBranch;

  SoundBranch root;
  public SoundBranch root() {return root;}

 public void setUp() {
    Sound clap = new Sound(
        FileChooser.getMediaPath("clap-q.wav"));
    Sound chirp = new Sound(
        FileChooser.getMediaPath("chirp-2.wav"));
    Sound rest = new Sound(
        FileChooser.getMediaPath("rest-1.wav"));
    Sound snap = new Sound(
        FileChooser.getMediaPath("snap-tenth.wav"));
    Sound clink = new Sound(
        FileChooser.getMediaPath("clink-tenth.wav"));
    Sound clave = new Sound(
        FileChooser.getMediaPath("clave-twentieth.wav"));
    Sound gong = new Sound(
        FileChooser.getMediaPath("gongb-2.wav"));
    Sound bassoon = new Sound(
        FileChooser.getMediaPath("bassoon-c4.wav"));
    Sound is = new Sound(
        FileChooser.getMediaPath("is.wav"));
    Sound aah = new Sound(
        FileChooser.getMediaPath("aah.wav"));

    // Build the root
    root = new SoundBranch();
    SoundNode sn;

    // Build the first branch
    SoundBranch branch1 = new SoundBranch();
    // One node, containing 3 sounds appended
    // together to create ONE sound
    sn = new SoundNode(clap.
        append(rest).append(snap));
    branch1.addChild(sn);
    sn = new SoundNode(aah.
```

```
            append(snap).append(rest));
        branch1.addChild(sn);

        // Build our scaled branch
        scaledBranch = new ScaleBranch(1.0);
        sn = new SoundNode(clink.
            append(clave).append(gong));
        scaledBranch.addChild(sn);
        sn = new SoundNode(is.
            append(chirp).append(clap));
        scaledBranch.addChild(sn);

        // Build a third branch, our second SoundBranch
        SoundBranch branch2 =
            new SoundBranch();
        sn = new SoundNode(clap.
            append(snap).append(snap));
        branch2.addChild(sn);
        sn = new SoundNode(bassoon.
            append(snap).append(clap));
        branch2.addChild(sn);

        // Assemble the whole tree
        root.addChild(branch1);
        root.addChild(scaledBranch);
        root.addChild(branch2);
    }

    public void play(){
        root.playFromMeOn();
    }

    public void playScaled(double factor){
        scaledBranch.setFactor(factor);
        root.playFromMeOn();
    }
}
```

How it works: There are a lot of similarities between this class and the WolfAttackMovie class. Each create a root variable that holds the main branch of the tree. Some branches that need to be accessed between methods are declared in variables in the class. The setUp() methods in both classes have a very similar structure. Each creates a branch, creates the nodes that go in that branch, and then loads the nodes into the branch. SoundTreeExample may be a little confusing, in that each node *only* contains a single Sound, but in this example, each node's Sound is a collection of three appended sounds. It's still one Sound per SoundNode.

Once we create our tree, we can explore the structure of the tree by simply printing it out. All the objects in the sound tree have toString methods. Since we know the implementation of the tree, we can walk the children and next links to explore the whole tree.

```
> tree // Not very useful in itself
SoundTreeExample@92b1a1
> tree.root() // Way useful
SoundBranch (with child:
SoundBranch (with child:
SoundNode (with sound: Sound number of samples: 28568 and next:
SoundNode (with sound: Sound number of samples: 46034 and next:
null and next:
ScaleBranch (1.0) SoundBranch (with child:
SoundNode (with sound: Sound number of samples: 47392 and next:
SoundNode (with sound: Sound number of samples: 32126 and next:
null and next:
SoundBranch (with child:
SoundNode (with sound: Sound number of samples: 8452 and next:
SoundNode (with sound: Sound number of samples: 28568 and next:
null and next: No next))) and next: No next)
> tree.root().children // All the children of the root
SoundBranch (with child:
SoundNode (with sound:
Sound number of samples: 28568 and next:
SoundNode (with sound:
Sound number of samples: 46034 and
next: null and next:
ScaleBranch (1.0) SoundBranch (with child:
SoundNode (with sound:
Sound number of samples: 47392 and next:
SoundNode (with sound:
Sound number of samples: 32126 and next: null and next:
SoundBranch (with child: SoundNode (with sound:
Sound number of samples: 8452 and next:
SoundNode (with sound:
Sound number of samples: 28568 and next: null and next: No next)))
> tree.root().children.getNext() // Second branch on
ScaleBranch (1.0) SoundBranch (with child:
SoundNode (with sound:
Sound number of samples: 47392 and next:
SoundNode (with sound:
Sound number of samples: 32126 and next: null and next:
SoundBranch (with child:
SoundNode (with sound:
Sound number of samples: 8452 and next:
SoundNode (with sound:
Sound number of samples: 28568 and
next: null and next: No next))
> tree.root().children.getNext().getNext() \\ 3rd Branch
```

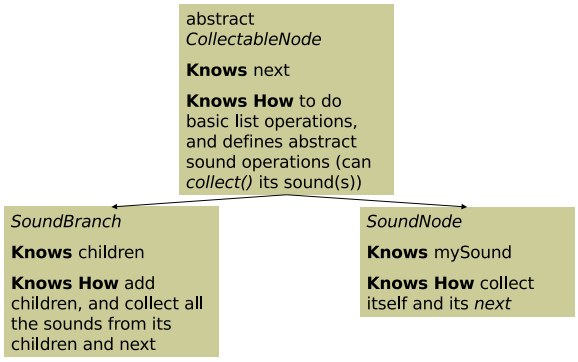

Figure 10.11: The core classes in the CollectableNode class hierarchy

```
SoundBranch (with child:
SoundNode (with sound:
Sound number of samples: 8452 and next:
SoundNode (with sound:
Sound number of samples: 28568 and next: null
and next: No next)
> tree.root().children.getNext().getNext().getNext() \\ 4th branch
null
```

Implementing a Sound Tree

How we build a tree of sounds is very much like how we built a tree of pictures.

- Set up a general *node* abstract superclass that all other node and branch classes inherit from. In our sound tree, this superclass is CollectableNode—a node from which a sound can be collected.
- Create a *leaf* node class that will store our data of interest (sounds). Here, that's a SoundNode
- Create a *branch* node that will store collections of leaves and references to other branches—a SoundBranch (Figure 10.11).
- Create (as we wish) *branch nodes with operations* that do things to the children of this branch. We have one example of a branch with operations, ScaleBranch (Figure 10.12).

Let's go through these classes in turn. We should note that much of the CollectableNode class hierarchy looks much like the code in the DisplayableNode class hierarchy.

* * *

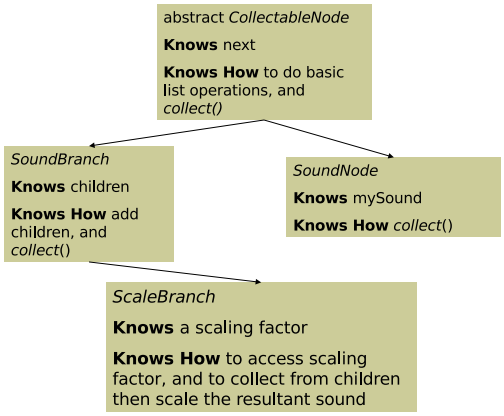

Figure 10.12: Extending the class hierarchy with ScaleBranch

Example Java Code: **CollectableNode**

Program Example #86

```
/**
 * Stuff that all nodes and branches in the
 * sound tree know.
 **/
abstract public class CollectableNode {
  /**
   * The next branch/node/whatever to process
   **/
  public CollectableNode next;

  /**
   * Constructor for CollectableNode just sets
   * next to null
   **/
  public CollectableNode(){
    next = null;
  }

 /**
   * Methods to set and get next elements
   * @param nextOne next element in list
   **/
  public void setNext(CollectableNode nextOne){
    this.next = nextOne;
  }

  public CollectableNode getNext(){
```

```
    return this.next;
  }

  // All the rest of the linked list
  // methods are there, too: insertAfter(), last()...

 /**
   * Play the list of sound elements
   * after me
   **/
  public void playFromMeOn(){
    this.collect().play();
  }

  /**
   * Collect all the sounds from me on
   **/
  abstract public Sound collect();

}
```

How it works: For the most part, CollectableNode is simply another linked list node class. It has a next link and lots of linked list methods. In addition, it defines abstract methods for collect()—the method for collecting a Sound from the node. In the abstract superclass CollectableNode, the method does nothing at all. The method playFromMeOn() is defined here, too. It simply plays what gets collected.

Example Java Code: **SoundNode**

Program Example #87

```
/*
 * SoundNode is a class representing a sound
 * node in a sound tree.
 **/
public class SoundNode extends CollectableNode {
  /**
   * The sound I'm associated with
   **/
  Sound mySound;

  /*
   * Make me with this sound
   * @param sound the Sound I'm associated with
   **/
  public SoundNode(Sound sound){
```

```
    super(); // Call superclass constructor
    mySound = sound;
  }

 /**
   * Method to return a string with informaiton
   * about this node
   */
  public String toString()
  {
    return "SoundNode (with sound: "+mySound+" and next: "+next;
  }

 /**
   * Collect all the sounds from me on,
   * recursively.
   **/
  public Sound collect(){
    if (this.getNext() == null)
    {return mySound;}
    else
    {return mySound.append(this.getNext().collect());}
  }
}
```

How it works: The class SoundNode models leaf nodes in our sound trees. Instances of SoundNode contains a Sound. The most interesting thing about SoundNode is how it defines toString() and collect().

- A SoundNode instance converts itself to a String by converting its Sound and its next to a String. That's easy to say, and that's why we define it that way. Tracing it takes some thinking about it.

- A SoundNode collects its sound by (a) if it has no next node (next is **null**), then returning its sound; (b) else, returning its sound appended with whatever its next will return when we ask it to collect(). Its this last part that is recursive. Most powerfully, though, the definition *is* easy to say and easy to understand—"When I'm told to collect, I grab me and whatever my buddy has to return." It's exactly how you collect papers when you're told to hand them to the end of the row: you stick yours on top of what your neighbor returns, then pass the whole stack to the next person.

Program Example #88

Example Java Code: **SoundBranch**

```
public class SoundBranch extends CollectableNode {
  /*
   * A list of children to draw
   */
  public CollectableNode children;

  /*
   * Construct a branch with children and
   * next as null
   **/
  public SoundBranch(){
    super(); // Call superclass constructor
    children = null;
  }
 /**
   * Method to add nodes to children
   **/
  public void addChild(CollectableNode child){
    if (children != null)
    {children.add(child);}
      else
      {children = child;}
  }
 /**
   * Method to return a string with informaiton
   * about this branch
   */
  public String toString()
  {
    String childString = "No children", nextString="No next";
    if (children != null)
    {childString = children.toString();}
    if (next != null)
    {nextString = next.toString();}

    return "SoundBranch (with child: "+childString+" and next: "+
      nextString+")";
  }

 /**
   * Collect all the sound from our children,
   * then collect from next.
   **/
  public Sound collect(){

    Sound childSound;

    if (children != null)
    {childSound = children.collect();}
    else
```

```
    {childSound = new Sound(1);}

    // Collect from my next
    if (this.getNext() != null)
    {childSound=childSound.append(this.getNext().collect());}

    return childSound;
  }
```

How it works: The class SoundBranch is the generic class for branches in a sound tree. Again, there is a similarity with the Branch class that we used with images.

- The definition for adding a child (addChild) is exactly the same as in Branch—if there's no children link, set it; else, add() to the children.
- The definition of toString() is a little complicated by the fact that we have to traverse both the children and next links to print a branch. We explicitly ask each variable to convert to toString() (being careful never to ask **null** to convert itself to a string—though it would be glad to do so). Then we return the string of these pieces concatenated together.
- How a SoundBranch collects all its sounds, in collect(), is straightforward to say. First, we want to collect all the children's sounds. If the node children is empty (**null**), we create a very small ($1/22,050$th of a second) sound to serve as a dummy, empty sound. If there are chilren, collect() from the children. We then return the childSound appended with the collection of sounds from next. In short form, a SoundBranch collects sounds by collecting all of its children's sounds (if there are any children) and all of its sibling's sounds, and return them appended together.

Program Example #89

Example Java Code: **ScaleBranch**

```
public class ScaleBranch extends SoundBranch {

  /** Amount to scale **/
  double factor;

  /**
   * Construct a branch with this factor
   **/
  public ScaleBranch(double nufactor){
```

```
    super(); // Call superclass constructor
    this.factor = nufactor;
  }

  /** Accessors **/
  public double getFactor() {return this.factor;}
  public void setFactor(double nufactor) {this.factor = nufactor;}

 /**
   * Collect all the sound from our children,
   * then collect from next. Scale the children
   **/
  public Sound collect(){

    Sound childSound;

    if (children != null)
    {childSound = children.collect().scale(factor);}
    else
    {childSound = new Sound(1);}

    // Collect from my next
    if (this.getNext() != null)
    {Sound nextSound=this.getNext().collect();
    childSound = childSound.append(nextSound);}

    return childSound;
  }

 /**
   * Method to return a string with information
   * about this branch
   */
  public String toString()
  {
    return "ScaleBranch ("+factor+") "+super.toString();
  }

}
```

How it works: The class ScaleBranch is a kind of SoundBranch, so it is a branch that knows how to add children and how to collect those children's sounds. In addition, a ScaleBranch has a factor that it uses to scale the sound from its children—scaling it up in frequency or down. This change requires a slightly different constructor (for setting the scaling factor) and accessors. The biggest change is in the collect() method. Now, when children are gathered, they are also scaled:

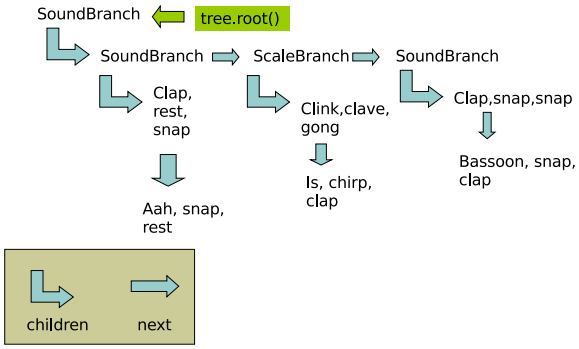

Figure 10.13: Starting out with tree.root().collect()

```
if (children != null)
{childSound = children.collect().scale(factor);}
else
{childSound = new Sound(1);}
```

Tracing a Recursive Tree Traversal

We have now seen how we can build and use a tree of sounds, and how that tree of sounds is implemented. In this section, we aim to understand how the tree traversal occurs dynamically. How is it that this simple code in the collect() methods traverses the whole tree?

We start from this code:

```
Welcome to DrJava.
> SoundTreeExample tree =
        new SoundTreeExample();
> tree.setUp();
> tree.root().collect().play()
```

The object in tree has a root() (an instance of the class SoundBranch, as we saw earlier) which is created in setUp(). We then ask the root to collect() all its sounds into one big Sound which we can then play(). How does that sound get collected?

When we start executing tree.root(). collect(), the tree and **this** looks like Figure 10.13. We start executing the below method for collect() with **this** pointing at the root.

```
public Sound collect(){
    Sound childSound;
    if (children != null)
    {childSound = children.collect();}
    else
    {childSound = new Sound(1);}
```

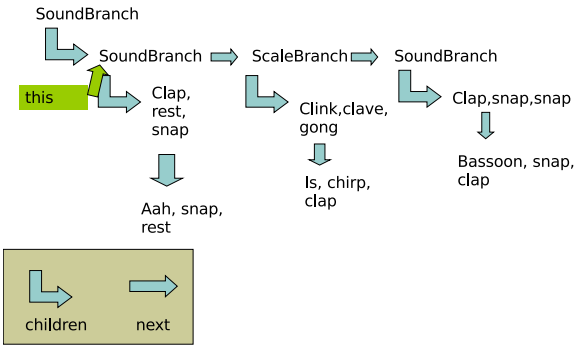

Figure 10.14: Asking the root's children to collect()

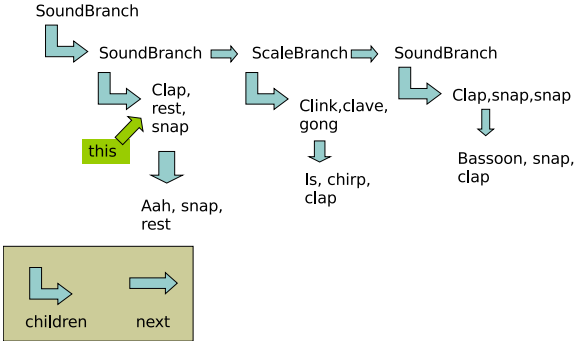

Figure 10.15: Asking the first SoundNode to collect()

Since the root clearly has children, we ask the children to collect(). Figure 10.14. The call to root(). collect() is frozen, as we have to wait to get children.collect() to return before the call to the root can complete. The same code gets executed as with the root, and since **this** is also a SoundBranch, the same code executes.

Again, **this** branch does have children, so we ask the children.collect() (Figure 10.15). Now, we're executing a different collect() method, because now **this** points at a SoundNode. So, we execute this version:

```
public Sound collect(){
    if (this.getNext() == null)
    {return mySound;}
    else
    {return mySound.append(this.getNext().collect());}
  }
```

The current **this** does have a next, so we need to collect() from there before we can finish this method. We move on to the next SoundNode (Figure 10.16). This one has no next, so we return "Aah, snap, rest" (all ap-

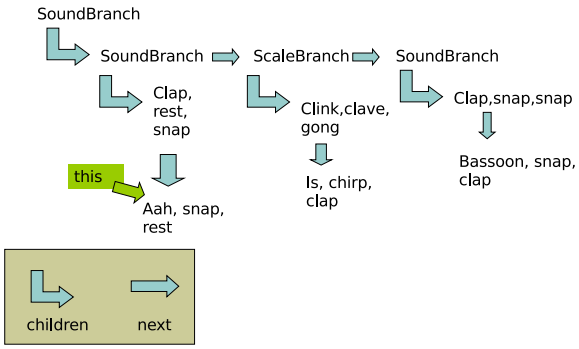

Figure 10.16: Asking the next SoundNode to collect()

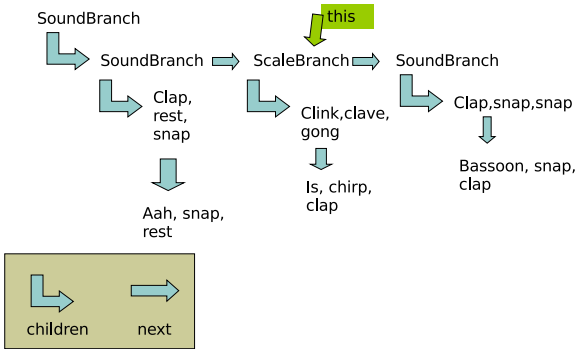

Figure 10.17: Collecting from the next of the SoundBranch

pended together as one Sound object).

At this point, we're back in the position of Figure 10.15, but later in the method collect(). We now have collected the sound from the next, so we can append **this** sound. We now return "clap, snap, rest" with "aah, snap, rest."

We're now back at the position of Figure 10.14. We now have the children's sound, so we can finish the SoundBranch's collect() method.

```
    // Collect from my next
    if (this.getNext() != null)
    {Sound nextSound=this.getNext().collect();
    childSound = childSound.append(nextSound);}

    return childSound;
  }
```

This SoundBranch *does* have a next, so we again freeze this method invocation while we ask **this**.getNext().collect(). We are now collecting from the ScaleBranch that is next to the SoundBranch (Figure 10.17).

We know something about what will happen next. The collect() method

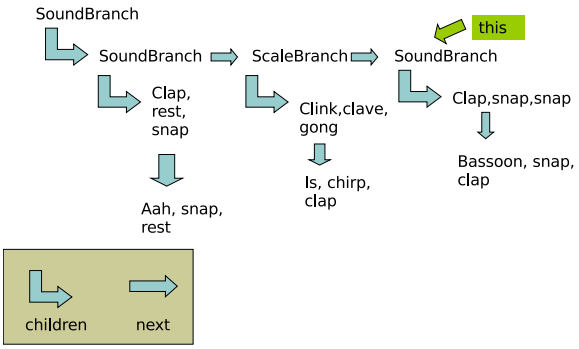

Figure 10.18: Collecting from the last SoundBranch

in ScaleBranch will gather up the sound from the children list. Then that resultant sound will be scaled.

```
public Sound collect(){
    Sound childSound;
    if (children != null)
    {childSound = children.collect().scale(factor);}
    else
    {childSound = new Sound(1);}
```

We can see from the tree that we will gather "clink, clave, gong" appended to "is, chirp, clap." That will get scaled to whatever factor is in the ScaleBranch. Then the ScaleBranch collect() method will finish:

```
    // Collect from my next
    if (this.getNext() != null)
    {Sound nextSound=this.getNext().collect();
    childSound = childSound.append(nextSound);}
    return childSound;
}
```

This is the same as in the collect() method of SoundBranch, so we know what's going to happen here. The ScaleBranch invocation of collect() stops executing and waits for **this**.getNext().collect() to execute. We ask the last SoundBranch to collect() (Figure 10.18).

It's worthwhile to consider just what methods are paused, frozen, waiting for other methods to finish. We call that list of methods that are currently pending the *stack trace*. These are quite literally in a *stack*. The last one on must be the first one popped. So, as of Figure 10.18, we have methods in play:

- The currently executing method, the call to collect() on the last SoundBranch.
- The call to collect() on the ScaleBranch is waiting for the collection from its next.

- The call to collect() on the first SoundBranch is waiting for the collection from the ScaleBranch.

- And the call that started it all—the root SoundBranch is waiting for the collection from its children.

We know that calling collect() on the last SoundBranch will result from collecting its children's sounds: "clap, snap, snap" appended with "bassoon, snap, clap" (Figure 10.18). This last SoundBranch has no next! So this call simply returns the sound "clap, snap, snap, bassoon, snap, clap."

We return to the state of Figure 10.17 and pop the method off the stack. We can now finish the call to collect() on the ScaleBranch. We return back up "clink,clave,gong,is,chirp,clap" scaled by the factor, appended with "clap, snap, snap, bassoon, snap, clap."

We now pop the next method off the stack, and we're at Figure 10.14. We take the sound from the next (the ScaleBranch and the rest of the tree), and append the sound from its children. So it returns "clap,rest,snap,aah,snap,rest", plus "clink,clave,gong,is,chirp,clap" scaled by the factor, plus "clap, snap, snap, bassoon, snap, clap."

We pop the last method off the stack—we're at the collect() of the root. Obviously, the root has no next, so we simply return the sound from the root's children: "clap,rest,snap,aah,snap,rest", plus "clink,clave,gong,is,chirp,clap" scaled by the factor, plus "clap, snap, snap, bassoon, snap, clap." And that's the sound that plays.

What we just traced might be called an *in-order traversal*. We visited the children, did whatever the branch needed to do (e.g., scale), then processed the next. There are different orderings of traversals. Imagine a form of ScaleBranch that scaled the result from the next rather the children. We will visit more of these traversals in the next chapter.

Where we're going next

Take a look at DrawableNode and CollectableNode. Pretty darn similar, aren't they? Duplicated code is a bad idea for several reasons:

- Duplicated code is hard to maintain. Let's say that we figured out a better way to do add() or reverse(). Right now, we have nearly identical code in two different classes, so we would need to fix both of those. What are the odds that we make a mistake at some point and forget to fix one of them when we fix the other?

- Duplicated code is a waste of space. Why should the exact same code be in memory in two different places.

- Duplicated code strains our notion of *responsibility-driven design* that is important for object-oriented programming. Whose responsibility is it to provide add()? Is it the responsibility of both DrawableNode and

CollectableNode? That seems odd. Rather, it should be the responsibility of some third class, that both of these classes use. That's where we're going in the next chapter.

In the next chapter, we will correct this problem, and make it easier to create more linked lists and trees in the future. Later, we will find that graphical user interfaces are *also* trees, and that different kinds of traversals of the same graphical user interface tree creates different window appearances.

Ex. 14 — Change the replace method so that it actually compares the sounds (sample-by-sample) rather than simply comparing the filenames.

Ex. 15 — Implement a subclass of SoundBranch called ReverseBranch that reverses the sound returned from collecting the children's sounds. Build a sound tree example using your new class.

Ex. 16 — Implement a subclass of SoundBranch called NormalizeBranch that normalizes volume returned from collecting the children's sounds. Build a sound tree example using your new class.

Ex. 17 — Implement a subclass of SoundBranch called VolumeChangeBranch that remembers a factor for use in increasing or decreasing the volume returned from collecting the children's sounds. Build a sound tree example using your new class.

Ex. 18 — Create a new version of ScaleBranch that scales its next rather than its children. Build a sound tree example using your new class.

Ex. 19 — Record some individual sounds (singing perhaps?) that represents verses and chorus of some song. Use a SoundTree to organize these sounds into the complete song with the right structure.

11 Generalizing Lists and Trees

Chapter Learning Objectives

In the last two chapters, we used trees to create an animation (the DrawableNode class hierarchy) and a complex sound structure (the CollectableNode class hierarchy). In this chapter, we create a generalized class that represents any kind of linked list structure. We will then go on to explain how to create generalized tree structures that are particularly efficient for some tasks (like searching).

The computer science goals for this chapter are:

- To *factor* out common functionality from two classes to create a new abstract superclass.
- To develop strategies for how to respond to Java compiler errors.
- To understand the relative characteristics of arrays, linked lists, and trees for various manipulations.
- To use a binary tree structure and understand its value in a search tree.
- To explore different kinds of traversals on binary trees.

11.1 Refactoring a General Linked List Node Class

We are going to remove the duplication between DrawableNode and CollectableNode by creating a new class, LLNode, that has the responsibility of being a linked list node. LLNode will be an abstract superclass—we'll never want just an LLNode (for one thing, it will have no data—it will just be a next). There are several advantages to this structure:

- We remove the duplication of code between DrawableNode and CollectableNode.
- We push the responsibility of being a linked list node to a class that bears just that responsibility.
- Once we create an LLNode class, we can create a linked list of anything by simply subclassing LLNode.

Creating an LLNode class is pretty easy. Certainly, LLNode will need a next instance variable. We'll simply copy-paste the linked list code from either of DrawableNode or CollectableNode, then change all the appropriate variable types to LLNode.

Program Example #90

Example Java Code: **LLNode, a generalized linked list node class**

```
abstract public class LLNode{
  /**
   * The next branch/node/whatever to process
   **/
  public LLNode next;

  /**
   * Constructor for LLNode just sets
   * next to null
   **/
  public LLNode(){
    next = null;
  }

  /**
   * Methods to set and get next elements
   * @param nextOne next element in list
   **/
  public void setNext(LLNode nextOne){
    this.next = nextOne;
  }

  public LLNode getNext(){
    return this.next;
  }

  /** Method to remove node from list, fixing links appropriately.
   * @param node element to remove from list.
   **/
  public void remove(LLNode node)
  {
    if (node==this)
    {
      System.out.println("I can't remove the first node from the list.");
      return;
    };

    LLNode current = this;
    // While there are more nodes to consider
```

```
    while (current.getNext() != null)
    {
      if (current.getNext() == node){
        // Simply make node's next be this next
        current.setNext(node.getNext());
        // Make this node point to nothing
        node.setNext(null);
        return;
      }
      current = current.getNext();
    }
  }

  /**
   * Insert the input node after this node.
   * @param node element to insert after this.
   **/
  public void insertAfter(LLNode node){
    // Save what "this" currently points at
    LLNode oldNext = this.getNext();
    this.setNext(node);
    node.setNext(oldNext);
  }

  /**
   * Return the last element in the list
   **/
    public LLNode last() {
      LLNode current;

      current = this;
      while (current.getNext() != null)
      {
        current = current.getNext();
      };
      return current;
  }
  /**
   * Return the count of the elements in the list
   **/
    public int count() {
      LLNode current;
      int count = 1;

      current = this;
      while (current.getNext() != null)
      {
        count++;
        current = current.getNext();
```

```
    };
    return count;
}

/**
 * Add the input node after the last node in this list.
 * @param node element to insert after this.
 **/
public void add(LLNode node){
  this.last().insertAfter(node);
}

/**
 * Reverse the list starting at this,
 * and return the last element of the list.
 * The last element becomes the FIRST element
 * of the list, and THIS goes to null.
 **/
  public LLNode reverse() {
    LLNode reversed, temp;

  // Handle the first node outside the loop
  reversed = this.last();
  this.remove(reversed);

  while (this.getNext() != null)
  {
    temp = this.last();
    this.remove(temp);
    reversed.add(temp);
  };

  // Now put the head of the old list on the end of
  // the reversed list.
  reversed.add(this);

  // At this point, reversed
  // is the head of the list
  return reversed;
}
```

Here's where it gets interesting. Can we now make CollectableNode and DrawableNode subclasses of LLNode, rip out all the replicated linked list code from CollectableNode and DrawableNode, *and then* make our WolfAttackMovie animation and sound tree examples work again? The process we're engaging in is called *refactoring*—we are moving replicated code *up* in the class

hierarchy, and making sure that everything still works afterward.

Making WolfAttackMovie work again

We'll start with the animation. We change DrawableNode in two ways:

- We change the class definition to extend LLNode.
- We remove the linked list code. There's a bit more to do here beyond simply deleting methods like add(). For example, we remove the definition of the next field, we change the constructor to simply call the **super**.

Example Java Code: **DrawableNode, with linked list code factored out** *Program Example #91*

```
/**
 * Stuff that all nodes and branches in the
 * scene tree know.
 **/
abstract public class DrawableNode extends LLNode {

  /**
   * Constructor for DrawableNode just sets
   * next to null
   **/
  public DrawableNode(){
    super();
  }

  /**
   * Use the given turtle to draw oneself
   * @param t the Turtle to draw with
   **/
  abstract public void drawWith(Turtle t);
  // No body in the superclass

  /**
   * Draw on the given picture
   **/
  public void drawOn(Picture bg){
    Turtle t = new Turtle(bg);
    t.setPenDown(false);
    this.drawWith(t);
  }

}
```

This new version of DrawableNode is much smaller and seems more appropriate for its responsibility. If the class LLNode now has the responsbility of "Being a linked list node," then class DrawableNode has the responsibility of "Being a linked list node that can be drawn." The amount of code and the methods for that, as seen above, seems appopriate for that responsibility.

When we click COMPILE now, it doesn't work. We get a lot of errors. Refactoring doesn't come for free.

- We get two errors in HBranch. The first one looks like this:

```
HBranch.java:38: incompatible types
found   : LLNode
required: DrawableNode
```

It turns out that there are two errors in the method that the above error points at, and they're both really the same thing.

```
public void drawWith(Turtle pen){
  DrawableNode current = children;

  // Have my children draw
  while (current != null){
    current.drawWith(pen);
    pen.moveTo(pen.getXPos()+gap,pen.getYPos());
    current = current.getNext(); // Error here, line 38
  }

  // Have my next draw
  if (this.getNext() != null)
  {current = this.getNext(); // Error on this line, too
    current.drawWith(pen);}
}
```

The problem is that we are going to try to call drawWith() with the object referenced in current which comes from getNext(). The method getNext() now returns type LLNode, yet current is of type DrawableNode. We *need* current to be a DrawableNode—general linked lists don't know how to drawWith(). That's what's meant by INCOMPATIBLE TYPES: getNext() returns an LLNode, and we're stuffing it into a DrawableNode variable. Now, we know that this will always work—all the nodes linked up to a DrawableNode will, in fact, be kinds of DrawableNodes. We have to tell Java that, by *casting*.

```
public void drawWith(Turtle pen){
  DrawableNode current = children;

  // Have my children draw
```

```
        while (current != null){
          current.drawWith(pen);
          pen.moveTo(pen.getXPos()+gap,pen.getYPos());
          current = (DrawableNode) current.getNext();
        }

        // Have my next draw
        if (this.getNext() != null)
        {current = (DrawableNode) this.getNext();
          current.drawWith(pen);}
      }
    }
```

- The second set of errors is identical to the first, just now in VBranch rather than in HBranch. (This does suggest that the drawWith code in those two classes is nearly identical, and we could further refactor these two classes.) We similarly have incompatible types in drawWith() because our current variable is an instance of DrawableNode but getNext() returns an LLNode. The fix is the same—we add casting.

No more compiler errors, so let's try to make our animation.

```
> WolfAttackMovie wam = new WolfAttackMovie()
> wam.setUp()
```

We get a new error, at *runtime*.

```
NoSuchMethodError: DrawableNode.add(LDrawableNode;)V
  at Branch.addChild(Branch.java:37)
  at WolfAttackMovie.setUp(WolfAttackMovie.java:39)
```

That is undeniably a strange error. Let's recompile Branch. Now, we get an error that we have seen before:

```
Branch.java:53: incompatible types
found   : LLNode
required: DrawableNode
```

It turns out to be the exact same error in the exact same place: drawWith() uses a variable current of type DrawableNode, but getNext() returns an LLNode. So, we have to add the casts here, too—same places, in fact. (Again, this suggests the need for refactoring in the branch classes.)

We can try again with WolfAttackMovie, as we did in a previous chapter. This time, we are rewarded with scenes of doggies attacking a village until the brave hero appears. We have successfully refactored the DrawableNode class hierarchy.

Making sound trees work again

Now, let's shift our attention to sound trees. We start with class CollectableNode. Just like with DrawableNode, we take two steps:

- We change the class definition to extend LLNode.
- We remove the linked list code.

Program Example #92

Example Java Code: **CollectableNode, with linked list code factored out**

```
/**
 * Stuff that all nodes and branches in the
 * sound tree know.
 **/
abstract public class CollectableNode extends LLNode {

  /**
   * Constructor for CollectableNode just sets
   * next to null
   **/
  public CollectableNode(){
    super();
  }

  /**
   * Play the list of sound elements
   * after me
   **/
  public void playFromMeOn(){
    this.collect().play();
  }

  /**
   * Collect all the sounds from me on
   **/
  abstract public Sound collect();
}
```

The new version of CollectableNode is even smaller than the new version of DrawableNode. For the most part, all CollectableNode really does is to define playFromMeOn() (which is only a single line) and declare the abstract method collect().

Perhaps surprisingly, when we compile the new CollectableNode and SoundTreeExample, no errors arise! The error occurs at runtime, when we try to use it:

```
> SoundTreeExample ste = new SoundTreeExample()
> ste.setUp()
NoSuchMethodError: CollectableNode.add(LCollectableNode;)V
  at SoundBranch.addChild(SoundBranch.java:37)
  at SoundTreeExample.setUp(SoundTreeExample.java:27)
```

So, we open up SoundBranch and recompile that. Now, we get a compiler error in SoundBranch—one we've seen before.

```
SoundBranch.java:58: incompatible types
found   : LLNode
required: CollectableNode
```

The method at line 58 is in collect().

```
public Sound collect(){

  Sound childSound;
  CollectableNode node;

  if (children != null)
  {childSound = children.collect();}
  else
  {childSound = new Sound(1);}

  // Collect from my next
  if (this.getNext() != null)
  { node=this.getNext(); // ERROR IS HERE
    childSound=childSound.append(node.collect());}

  return childSound;
}
```

The variable node has type CollectableNode, and getNext() (now) returns an LLNode. We can repair this with a simple cast: node=(CollectableNode) **this**.getNext().

When we try to execute a sound tree example, we get the next error, at runtime.

```
> SoundTreeExample ste=new SoundTreeExample()
> ste.setUp()
> ste.play()
NoSuchMethodError: SoundNode.getNext()LCollectableNode;
  at SoundNode.collect(SoundNode.java:34)
  at SoundBranch.collect(SoundBranch.java:52)
```

We'll use a similar strategy as we did last time. The error suggests that the error is in SoundNode. Let's recompile that class. Yes, now we do get a compile-time error.

```
SoundNode.java:37: incompatible types
found   : LLNode
required: SoundNode
```

Line 37 is in collect().

```
public Sound collect(){
  SoundNode nextNode;
  if (this.getNext() == null)
  {return mySound;}
  else
  {nextNode = this.getNext(); // ERROR HERE
    return mySound.append(nextNode.collect());}
}
```

Same error here as we have seen before, with the same fix: nextNode = (SoundNode) **this**.getNext(); We try again with a compilation and an execution.

```
> SoundTreeExample ste=new SoundTreeExample()
> ste.setUp()
> ste.play()
NoSuchMethodError: ScaleBranch.getNext()LCollectableNode;
  at ScaleBranch.collect(ScaleBranch.java:45)
  at SoundBranch.collect(SoundBranch.java:59)
```

The error is in ScaleBranch to be sure, and we can probably guess where the error will be. When we compile ScaleBranch, we get a slightly different error:

```
ScaleBranch.java:46: cannot find symbol
symbol  : method collect()
location: class LLNode
```

What this error says is that our code currently asks an LLNode to collect(). CollectableNode instances know how to collect(), not LLNode instances. Here's what the actual line looks like.

```
public Sound collect(){

  Sound childSound;

  if (children != null)
  {childSound = children.collect().scale(factor);}
  else
  {childSound = new Sound(1);}

  // Collect from my next
  if (this.getNext() != null)
  {Sound nextSound=(this.getNext()).collect(); // ERROR HERE
  childSound = childSound.append(nextSound);}

  return childSound;
}
```

This is actually a similar problem as we had earlier, and se need a similar fix. **this**.getNext() returns an LLNode, and LLNode instances don't know how to collect(). We need a cast. Because of the statement, the cast looks a little more complex. The working line with a cast looks like this: Sound nextSound=((CollectableNode) **this**.getNext()).collect();.

Now, finally, we can execute:

```
> SoundTreeExample ste=new SoundTreeExample()
> ste.setUp()
> ste.play()
```

We are rewarded with a gong-ing mess of noise. We have successfully refactored both class hierarchies. We have defined a generalized linked list node, removed the linked list content from both class hierarchies, and made everything work again.

11.2 Making a New Kind of List

Now that we have a generalized LLNode class, we can create new kinds of linked lists easily. We never have to write add() or remove() again. Instead, we simply subclass LLNode. Our subclass should define the data that we want to store in the linked list.

As an example, let's use the Student class that we defined back in Chapter 2 and create a linked list of students. We define a StudentNode class that extends LLNode and stores a Student instance for each node.

Example Java Code: **StudentNode class** *Program Example #93*

```
public class StudentNode extends LLNode {

  // Constructor
  public StudentNode(Student pupil){
    super();
    this.setStudent(pupil);
  }

  private Student me;

  public Student getStudent(){
    return me;
  }

  public void setStudent(Student someone){
    me = someone;
  }
```

```
  public static void main(String[] args){
    // Make our first student
    Student fred = new Student("Fred");
    // Create the students list with the first student
    StudentNode students = new StudentNode(fred);

    /* Add several more students */
    students.add(new StudentNode(new Student("Wilma")));
    students.add(new StudentNode(new Student("Barney")));
    students.add(new StudentNode(new Student("Betty")));

    /* Print out first student */
    System.out.println(students.getStudent());
    /* Print out third student */
    System.out.println(students.getNext().getNext().getStudent());
  }
}
```

How it works: The class declaration was obvious: **class** StudentNode **extends** LLNode. We declare a **private** variable me which has a type Student. Our constructor for StudentNode sets the instance variable to the input student, using the setter that we also define for manipulating the Student in the node.

The main() method simply creates a few nodes (with a few students), then prints them out for testing. However, the simple code above won't work. When we compile it, we get the error:

```
StudentNode.java:33: cannot find symbol
symbol  : method getStudent()
location: class LLNode
```

We have seen an error like this previously. It is saying that the class LLNode does not understand getStudent(). That's obvious—the question is, "Where are we asking an LLNode to getStudent()?" The error is in the last line of main():

```
System.out.println(students.getNext().getNext().getStudent());
```

While students has type StudentNode, we recall that getNext() is in LLNode. It returns type LLNode. The solution, of course, is to cast. We need to cast the result of students.getNext().getNext() to StudentNode. Here's the rewritten line, spaced out over several lines to make the parentheses clear.

```
System.out.println((
                    (StudentNode)
                      (students.getNext().getNext())
                      )
                      .getStudent());
```

11.3 The Uses and Characteristics of Arrays, Lists, and Trees

At this point, we can start to summarize some of the characteristics of the various data elements that we have been discussing up until now. We have learned about arrays, linked lists, and trees.

Arrays are more compact than linked lists or trees. Arrays are just element after element after element in memory. There is no wasted space. Linked lists use additional memory to hold references to the next elements. Trees are even worse because they contain both next and children links.

If arrays are more compact, why would you ever want to use linked lists or arrays? Here are several reasons:

- If you don't know the maximum size of the collection of things *a priori*. A linked list or a tree can grow to any size—that's why they are often called *dynamic data structures*.
- If you want to be able to insert and delete into the middle of the collection easily. It is complicated and computationally expensive (in other words, it takes a lot of time) to move lots of elements around in an array.
- You don't need to have fast access to any particular element.

What applications have these characteristics? Lots!

- Order of elements on a slide in PowerPoint. You can SEND TO BACK or BRING FORWARD to change the order of any element in the linked list of elements on the screen.
- Order of video segments when you do non-linear video editing, as in iMovie or Windows Movie Maker. Think about the amount of memory required to store frames in a video—all those pixels, all that sound. For you to be able to drag and drop groups of frames so easily, it cannot be that all the frames are in a big array. It would take much more time to move frames around if that were true.
- Items in a toolbar. Have you ever re-configured your toolbar in an application? You simply drag and drop these icons into the list of icons. As easily as they are rearranged, inserted, and deleted, it is likely that items in a toolbar are stored in a linked list.
- Slides in a PowerPoint presentation. Just as it's too easy to drag segments of video around, it's too easy to drag around sets of slides in the slide organizer in Powerpoint. If slides were stored as an array, you would expect more of a delay as all those pixels and text are moved around, yet it takes not time at all. It's likely that slides are stored in a linked list.

The last point in that list of strengths of linked lists is particularly important: arrays are fast for accessing any element. To access the fifth element of an array is no faster than accessing the 105th. On the other hand, accessing the nth element of a linked list requires $O(n)$ accesses—you have to just walk one element to its next.

How about searching? What if you want to find a particular item in an array? If there is no order to the array or list, it is an $O(n)$ process to find the element—you simply search one piece after another. However, if the array is in a sorted order, you can use a *binary search*. You probably learned about a binary search in your first computing course.

Searching through a dictionary is a good way to depict a binary search. If you want to find a word ("eggplant" for example), you could simply check one page after the next. That's an $O(n)$ search—you just keep checking element after element for n elements. (On average, the word you are looking for will be halfway through the dictionary.) There's a smarter way.

- Open up the dictionary halfway through. Is the word you want on those pages? If not, is it before or after the halfway point? We can only answer this question because we know that a dictionary is in sorted order—"A" is at the beginning and "Z" is at the end.

- Take the first or second half of the dictionary, whichever way the desired word lays, and split that half in half. Ask the same questions: On this page, before, or after?

In general, a binary search lets you find the word in $O(log_2 n)$ tries. Since you split n in half each time, it's at most $log_2 n$ tries to get all the way down to the page where the word is. That's a lot faster than $O(n)$.

You can't get any real efficiences in searching a linked list. Even if the linked list is in sorted order, you can't get to the middle one (for example) any faster than just checking each node one-at-a-time from the beginning. Thus, there's no good answer for linked lists.

There is some hope for trees, however. If there is no order to the tree, then searching a tree for some element is just as slow as a linked list. There is a way of structuring trees so that they are as fast to search as a binary search on an array. More on that in the next subsection.

Examples of Tree Uses

What are trees good for, if they are less compact than arrays and no faster than linked lists? Trees have two huge benefits:

- Trees represent structure. Whether we consider that structure to be a hierarchy or just clustering, the branching character of a tree allows us to represent something that a linked list doesn't.

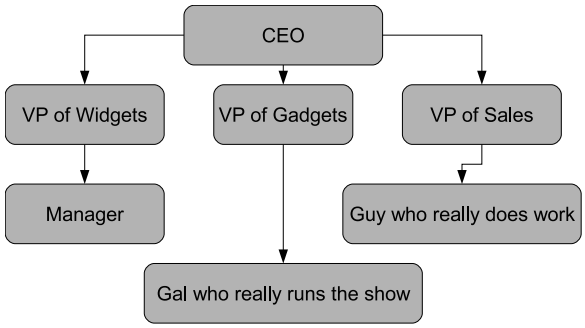

Figure 11.1: An example organization chart

- Branches in a tree can represent something apart from data, like the operations in our sound and image trees. That is a powerful ability to encode both structure and behavior in the same computational entity.

Some of the things that we can represent in a tree include:

- Representing how parts of music assemble to form a whole—we saw that earlier.
- Representing the elements of a scene (a *scene graph*)—again, we saw this earlier, and we know that that's how professional 3-D animators depict scenes.
- Representing the inheritance relationships among classes (a *class hierarchy*). You may not have thought about that when we were describing our classes. Look again at the descriptions of the DrawableNode or CollectableNode class hierarchies, and you see a clear tree structure.
- Files and directories on your hard disk—directories are essentially branches, files are leaves.
- Elements in an HTML page. If you know HTML, you know that a whole file splits into <head> and <body>. A <head> can contain (for example), a <title>. A <body> can have any number of subcomponents, such as a <p> paragraph which can contain <b> bold text or <i> italicized text. Thus, a document has two main branches, and sub-branches within those branches. That sounds like a tree.
- An organization chart ("orgchart") is clearly a tree (Figure 11.1)—a manager has some number of employees, and there are levels (hierarchies) of management.

An example that might be surprising is that a tree can represent an equation (Figure 11.2). Operators go in the branches and operands (numbers, variables) are in the leaves. In fact, this is how equations are often

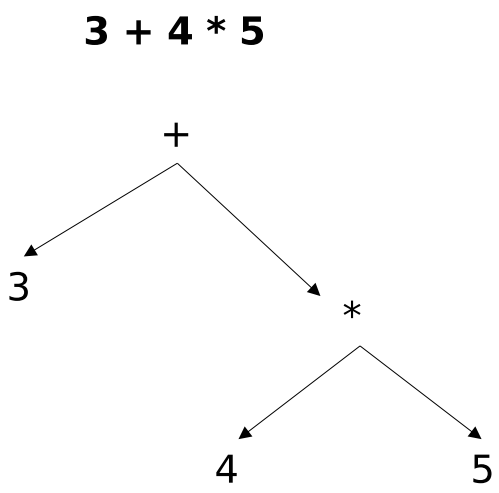

Figure 11.2: An equation represented as a tree

represented internally within a computer. The nice thing about representing equations with trees is that a simple *in-order traversal* of the tree recreates the equations *and* in the order that the operations should be performed. For example, in Figure 11.2, we would do the multiplication before the addition, which laws of mathematics would require us to do.

The links in a tree can have meanings. In the examples we have seen already, the links from parent node to child node have different meanings. In a class hierarchy, they indicate that the class represented by the parent node is a superclass of the class represented by the child node. In an organization chart, they indicate the parent is the boss and the children are the employees. In an equation tree, the links indicate that the result from the children will be used in applying the operation in the parent.

We can also use trees to represent *meaning*, where the links represent "the child is similar, but a specific case, of the parent." Consider a tree of words or phrases that represent meaning differences. Figure 11.3 represents a kind of taxonomy, an organization of meanings associated with the concept of "price." The same word "price" might represent what the customer pays versus what another company might pay.

Where might you use such a tree of meanings? Imagine that you want to create a website that "*crawls*" (visits and gathers information) various shopping or catalog sites to gather prices, so that you can compare the price of the same product at different sites. Maybe one store calls the price the "price" and the other one calls it the "consumer cost," and you want to avoid the store that talks about "retail price." A tree of meanings like this can be used to work out how your *web crawler* program should respond to

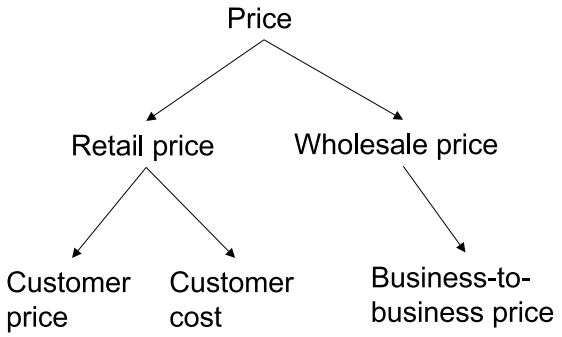

Figure 11.3: A tree of meanings

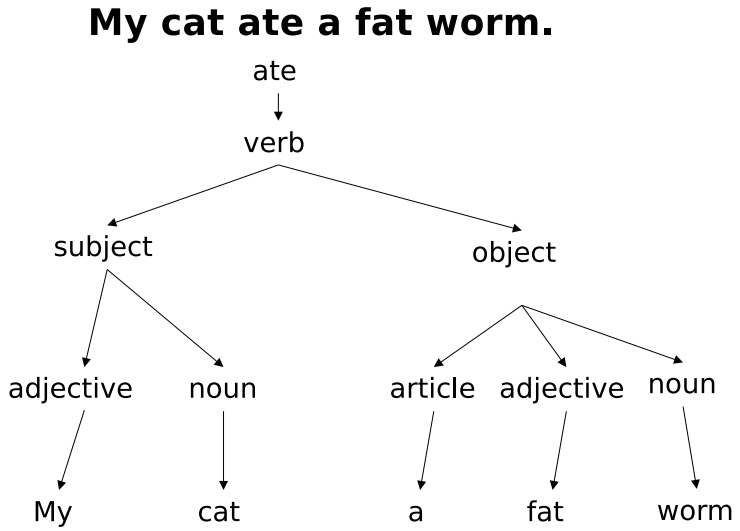

Figure 11.4: A sample sentence diagram

these different human terms.

For many of you readers, the notion of representing words in trees may be familiar from *sentence diagrams* that you may have used in your primary schooling (Figure 11.4)[1]. A sentence diagram explicitly labels the parts of the sentence (e.g., verb, object, subject, predicate phrase, and so on) with the actual words at the leaves or root of the tree—the boundaries.

A sentence diagram actually has computational advantages, too. Imagine that you work for an organization that is concerned with watching for

[1]There are a wide variety of sentence diagramming techniques and forms. The advantage of this one is that it is certainly unlike any that anyone actually uses.

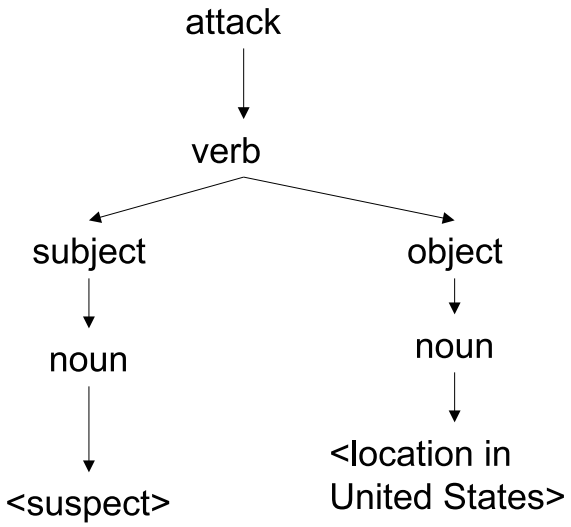

Figure 11.5: A query for a collection of sentence trees

signs of terrorist activity in the United States from captured text messages. Given the amount of captured text messages today, there are probably megabytes and volumes of messages. Do you just search for a phrase like "is going to attack"? How do you deal with synonyms of the word? What you really want to know is if the phrase refers to a location in the United States (and what that location is) as opposed to "is going to attack my homework this evening."

This problem is actually solvable with trees of the form that we have been talking about in this section. Imagine that you were able to take those enormous text message collections and figure out the meanings of the words so that you could build trees of all the sentences like Figure 11.4. You might represent what you want to know *also* as a tree, as in Figure 11.5. This query says that you want to know if "someone" (and that <angle brackets> indicates that you want to know whatever lands in this spot) is going to "attack" somewhere in the United States. What if the terrorists use another word for attack? That's where meaning taxonomies as in Figure 11.3 come in. As we find verbs that are similar to attack, we can check them out in a taxonomy, and if the other pieces fit (e.g., that the target is somewhere in the US), we declare a match.

Doing this kind of matching of pieces of various trees is called a *unification* algorithm. Unification is very powerful. The programming language *Prolog* is actually a language for specifying trees like these, functions as rules on trees, and a powerful form of unification.

Here is one last tree that you use all the time, though you may not have thought of it as a tree. A user interface in a modern computer window

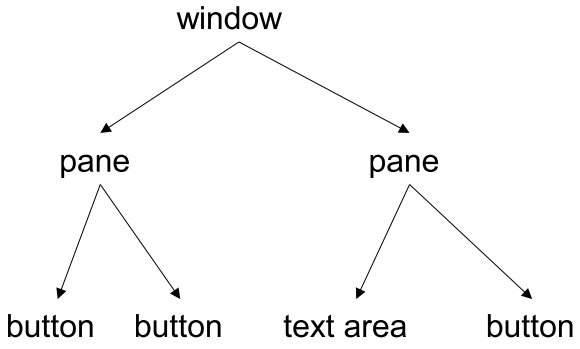

Figure 11.6: A user interface is a tree

is a tree (Figure 11.6). The whole window is usually broken into parts we call *panels*. Those panels might have a row of buttons (maybe for a toolbar), and another may hold a text input area and a SAVE button. That is actually a tree. You can actually take the same user interface tree and create a variety of different appearances for the window. Different *layout managers* will render the same user interface tree in different ways—we will see that in the next chapter.

11.4 Binary Search Trees: Trees that are fast to search

As we said in the previous section, we can structure arrays so that we can search them for something particular (some element) in $O(log_2 n)$. Lists are always $O(n)$ to search. We *can* structure trees in such a way that they are also $O(log_2 n)$ to search. We construct a *binary search tree* out of a *binary tree*.

A binary tree is so-named because every branch has at most *two* children (Figure 11.7). We explicitly label the links *left* and *right*. What data is in each of these nodes is left completely open—maybe it's some general string, some objects, some images or sounds, whatever.

The really interesting thing about a binary tree, particularly compared to our trees so-far, is that *any* node can be a branch. *Every* node has data associated with it, and a left link, and a right link. That means that any parent node can also be a child node (Figure 11.8). Any branch of a tree, then, is also a tree. It's always the same kinds of objects all the way down. That level of consistency or uniformity can be quite powerful in computation.

Binary trees have a bunch of interesting characteristics that computer scientists have studied over the years. Let's say that you have n nodes in a

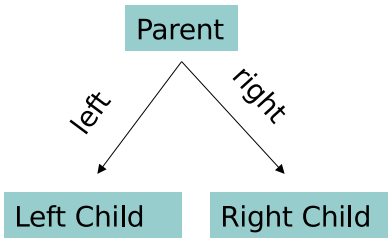

Figure 11.7: Simple binary tree

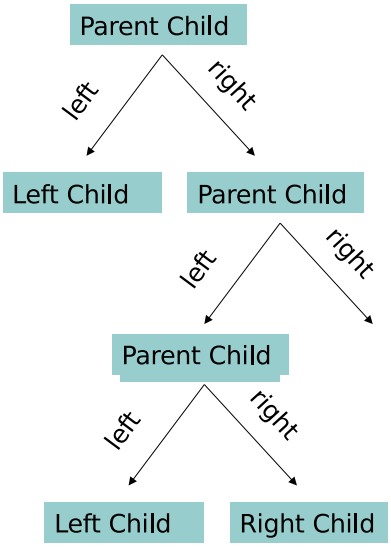

Figure 11.8: More complex binary tree

tree. What is the maximum number of levels or generations in that tree? (Think of the number of levels or generations as the number of nodes you pass through going from the root of the tree to its farthest away leaf.) Each node could only be linked by the left links, or all by the right links — it's just a linked list. Then the number of levels is n. The *minimum* number of levels, though, is $log_2 n + 1$. Try it—see if you can structure n nodes in fewer levels.

A binary tree is a great example of an ADT. Given what we have seen previously, you can probably imagine much of the definition of a binary tree.

- There is really only one class to define—some kind of TreeNode, since we know that all nodes are exactly the same, completely uniform, throughout the tree.

- There must be some way to getLeft and setLeft, and similarly getRight and setRight.
- There must be some way to getData and setData—whatever those data might be. One would probably imagine that the constructor for the node class would take data as input.
- Given that we are going to use this tree for storing data that we can find quickly, we might imagine that there will be a insert method that puts a piece of data into the right place in the tree—or maybe we call it an insertInOrder method that thus makes it clear that the data inserts in order. We would then (reflectively) expect a find method that finds the node that has a particular piece of data.

Given the above, one could start writing programs right now that could use a binary tree—even without seeing the implementation. There actually are several different kinds of implementations of trees. For example, there is an implementation of trees that works in a plain old array by computing indices in a crafty way[2]. The implementation doesn't really matter, as long as the above methods are there and work the way that you expect.

Of course, we are going to implement a binary tree as a TreeNode class with object references.

Example Java Code: **TreeNode, a simple binary tree**

Program Example #94

```
public class TreeNode {
  private String data;
  private TreeNode left;
  private TreeNode right;

  public TreeNode(String something){
    data = something;
    left = null;
    right = null;
  }
 // Accessors
  public String getData() {return data;}
  public void setData(String something){data = something;}

  public TreeNode getLeft() {return left;}
  public TreeNode getRight() {return right;}

  public void setLeft(TreeNode newleft){left = newleft;}
  public void setRight(TreeNode newright){right = newright;}
```

[2]Basically, have an array of strings (for example), and store the left child of index n at $2n$ and the right child at $2n + 1$.

```
  // Recursive traversal of the tree
  public String toString()
  {return
    "This:"+this.getData()+
  " Left: "+this.getLeft() +
  " Right: "+this.getRight();}
}
```

Let's test by building a small tree (just two nodes), and see if it prints correctly.

```
> TreeNode node1 = new TreeNode("george");
> node1
This:george Left: null Right: null
> TreeNode node1b = new TreeNode("alvin")
> node1.setLeft(node1b)
> node1
This:george Left: This:alvin Left: null Right: null Right: null
```

That generally is what we would expect. Now, let's use this binary tree to structure data so that we can search and find things very quickly. The structuring rule for a *binary search tree* is very simple: **The left side data is *less than* the data in the parent node, and the right side data is *greater than or equal to* the data in the parent node**. Structured like that, a binary search tree is like our dictionary—at each branch, we split the dictionary (tree) in half. At least, that's true if the tree is *well-formed*. We say more about a well-formed, *balanced* binary search tree a bit later.

Given the definition of how we want a binary search tree structured, the algorithm for inserting a new piece of data into a binary search tree is about searching for where the data *should* be, if it were there already, then putting it into place. The method insertInOrder is recursive. Because the whole tree is uniform (each parent node is a root of another tree, just a sub-tree of the whole tree's root), we can just pass the buck to the other nodes to do the right thing. The result is that the code is quite short.

How it works: First we ask, "Is the value to insert less than the current node's value?" If that's true, we look to see if there is a left branch. If there is, we ask the left branch to insert the data into place—we make a recursive call to insertInOrder. If there is no left branch, we know where to put the data that we want to insert—we insert it on the left. If the value to insert is greater than or equal to the current nodes value (which it must be if it's not less-than), then we check to see if there is something on the right branch. If there is, we ask that right branch node to do the insertInOrder. If there isn't, bingo! We put the node on the right.

Since we are working on strings here, we are going to have to compare strings in alphabetical order. There is a method on Strings to do this: compareTo(). The method compareTo is sent to a string, and takes a sec-

ond string as input to the method. The method returns a zero if the two strings are equal (have the same characters), positive if the input string comes before the string that the method is called on, and negative if the input string comes after. The value has to do with the number of letters (characters) between the two strings.

```
> "abc".compareTo("abc")
0
> "abc".compareTo("aaa")
1
> "abc".compareTo("bbb")
-1
> "bear".compareTo("bear")
0
> "bear".compareTo("beat")
-2
```

Example Java Code: **insertInOrder for a binary search tree**

Program Example #95

```
// Insert in order
  public void insert(TreeNode newOne){
    if (this.data.compareTo(newOne.data) > 0){
      if (this.getLeft() == null)
      {this.setLeft(newOne);}
      else
      {this.getLeft().insert(newOne);}}
    else {
      if (this.getRight() == null)
      {this.setRight(newOne);}
      else
      {this.getRight().insert(newOne);}
    }
  }
```

Let's try it out:

```
> TreeNode node1 = new TreeNode("george");
> TreeNode node2 = new TreeNode("betty");
> TreeNode node3 = new TreeNode("joseph");
> TreeNode node4 = new TreeNode("zach");
> node1
This:george Left: null Right: null
> node1.insert(node2)
> node1
This:george Left: This:betty Left: null Right: null Right: null
> node1.insert(node3)
```

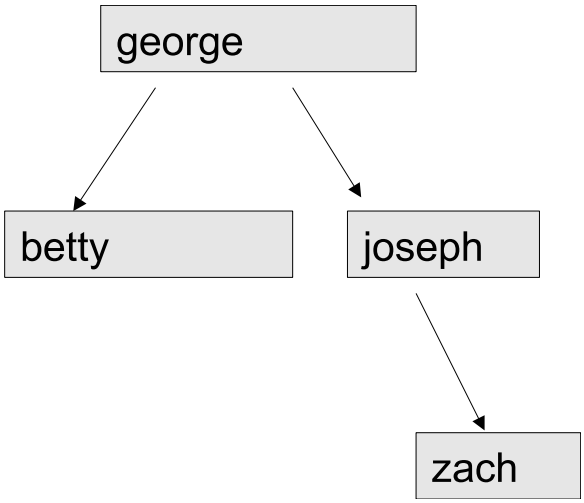

Figure 11.9: Tree formed by the names example

```
> node1
This:george Left: This:betty Left: null Right: null Right: This:joseph Left: null Ri
> node1.insert(node4)
> node1
This:george Left: This:betty Left: null Right: null Right: This:joseph Left: null Ri
```

The printing of node1 at the very end describes the whole tree. It may be hard to understand as such. You might compare it to the drawing of the tree in Figure 11.9.

Now that we have a tree that is formed well for scripting, we can try to write find() for this tree. The basic algorithm depends on the same structuring that we talked about earlier: smaller things down the left side, and bigger things down the right. Again, it's recursive because it's working on the uniform structure of the tree.

How it works: The method find() takes an input string to find. The method asks "Is the input less than 'me' (**this**.getData())?" If so, then stop and return this node. If not, then we want to compare the input string to the current data. If it's less, we find() down the left branch, and it greater than or equal, we search down the right branch. However, if the left or right node isn't there (e.g., we want to find() down the left and there is no left node), then we return **null** to indicate that the data was not found.

Program Example #96

Example Java Code: **find, for a binary search tree**

```
public TreeNode find(String someValue){
```

```
    if (this.getData().compareTo(someValue) == 0)
    {return this;}
    if (this.data.compareTo(someValue) > 0){
      if (this.getLeft() == null)
      {return null;}
      else
      {return this.getLeft().find(someValue);}}
    else {
      if (this.getRight() == null)
      {return null;}
      else
      {return this.getRight().find(someValue);}}
  }
```

Let's try it on the tree in Figure 11.9:

```
> node1.find("betty")
This:betty Left: null Right: null
> node1.find("mark")
null
```

If tree is well-ordered and well-structured, then searching in the tree should be an $O(log_2(n))$ process. Each decision splits the amount of data in half. From the top to the bottom of the tree should not take more than $1 + log_2(n)$ steps, so no more than that many checks.

We call that kind of tree as being *balanced*. A completely valid binary search tree might *not* be balanced—that is, it's *unbalanced*. Figure 11.10 is completely a valid binary search tree: no node has more than two children, left is less than the parent, and right is greater than the parent. This is the same tree as in Figure 11.9. How many searches will it take to find "zach" in this tree using find()? Just as many nodes as in the tree, n steps (where $n = 4$ here). Since everything is on the right, we just keep checking one node after the other—this is the same as searching a linked list.

What we want is a way of converting an unbalanced tree into a balanced tree, where roughly half of each sub-tree is in the left branch of the sub-tree and the other half is in the right branch of the sub-tree. We are not going to build this algorithm here. The key idea is that we have to *rotate* our nodes. If we were to rotate the right branch off "betty" in Figure 11.10, we would "rotate up" the node "joseph," moving "george" to the left and leaving "zach" on the right. That part isn't hard to understand or even implement. Completely balancing the tree involves rotating left and right to go from Figure 11.10 to Figure 11.9—for example, notice that the node "george" has to become the root of the tree, so another kind of rotation occurs from Figure 11.11 from Figure 11.10.

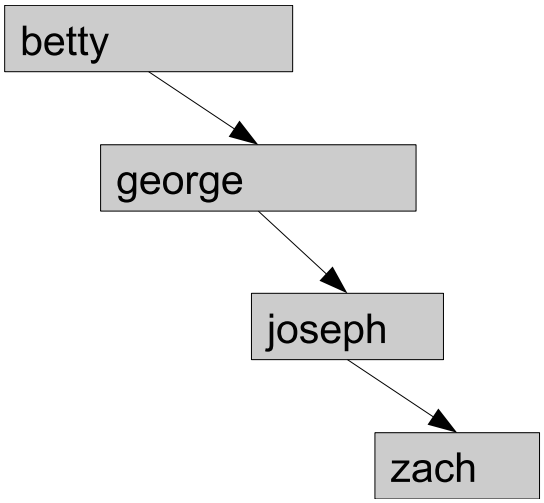

Figure 11.10: An unbalanced form of the last binary search tree

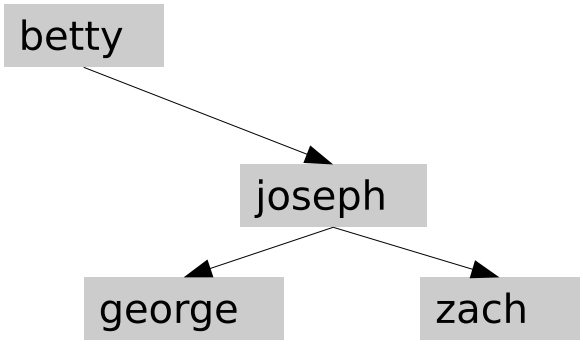

Figure 11.11: Rotating the right branch off "betty"

Traversals of Trees

We can take a binary search tree and print it out in alphabetical order. We use a process called *inorder traversal*—traverse the tree in (alphabetical) order. It's really pretty simple, if we are willing to do it recursively. From each node, the left side has to come before the current (**this**) node, and then the right side should be printed. That would be the order because left is less than **this** data, and right is greater than **this**.

Program Example #97

Example Java Code: **traverse, a binary tree in-order**

```
//In-Order Traversal
 public String traverse(){
   String returnValue = "";
   // Visit left
   if (this.getLeft() != null)
   {returnValue += " "+this.getLeft().traverse();}
   // Visit me
   returnValue += " "+this.getData();
   // Visit right
   if (this.getRight() != null)
   {returnValue += " "+this.getRight().traverse();}
   return returnValue;}
```

Let's try it on our binary tree from Figure 11.9:

```
> node1.traverse()
"  betty george  joseph  zach"
```

Do we have to do it that way? Of course not! We could visit ourself, then the left and then right. That's called *pre-order traversal*. We could also visit the left and then the right, and then ourself. That's called *post-order traversal*. We can think about other orderings as well.

Doing an in-order traversal of a tree makes sense. One can imagine wanting a list of everything in a tree. When we are working with trees of names, doing a pre-order or post-order traversal doesn't make much sense. However, it does make sense when there are certain other things in the tree, like the equation tree we saw earlier (Figure 11.2).

Here's an example of the power of different traversals on this kind of tree. If you do an in-order traversal of the equation tree Figure 11.12, you get $(3 * 4) + (x * y)$. That is fine and useful—that is an equation that makes sense. If you do a pre-order traversal of the same tree, you get $34 * xy * +$. That may look like gibberish *unless* you have ever used a *reverse Polish notation* (*RPN*) calculator, like some of Hewlett-Packard's popular calculators. The equation $34 * xy * +$ means "Push a 3 on the *stack*, then a 4, multiply two things on the stack and push the result back on the stack. Push the value of x on the stack, then y, multiply the two things on the stack and push the result back. Finally, add the two things on the stack and push the result back on." This turns out to be an efficient way of doing the same computation. A pre-order traversal of the same equation tree gives you the RPN form of the equation.

Trees can do anything

We now know a bunch of things that trees can do well:

- It is easy to do useful things with them.

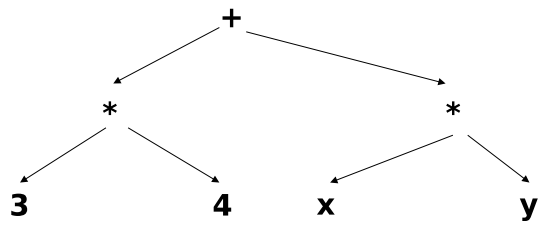

Figure 11.12: An equation tree for different kinds of traversals

  - Searching is quick.
  - We can use them to evaluate equations.

- Operations on trees are easily written, small, and recursive.
- We know interesting facts about them.

Binary trees can actually do just about anything. A binary tree can represent an n-ary tree, like the ones we used in earlier chapters. A binary tree can even be a list.

Imagine that we want a list (an ordered group of items) where we can add things to the front or end of the list. We can implement that with a linked list, of course. We can also implement this same structure with a binary tree. We make the structuring assumption that *earlier* items are to the left, and *later* items go to the right—a similar assumption to how we made a binary search tree. Here are the methods for doing that, addFirst() and addLast().

Program Example #98

Example Java Code: **addFirst and addLast, treating a tree as a list**

```
public void addFirst(TreeNode newOne){
   if (this.getLeft() == null)
   {this.setLeft(newOne);}
   else
   {this.getLeft().addFirst(newOne);}
 }

 public void addLast(TreeNode newOne){
   if (this.getRight() == null)
   {this.setRight(newOne);}
   else
   {this.getRight().addLast(newOne);}
 }
```

* * *

```
> TreeNode node1 = new TreeNode("the")
> node1.addFirst(new TreeNode("George of"))
> node1.addLast(new TreeNode("jungle"))
> node1.traverse()
"  George of the  jungle"
```

While binary trees are simple, they are actually quite powerful. There is great power in having a uniform structure—it allows us to write code in short form that actually works. By simply choosing the meaning of our left and right links, we can represent a wide variety of things. This chapter explains some of these.

Ex. 20 — How would you rewrite VBranch and HBranch so that there is less duplicated code between them? Could you have a general LayoutBranch that calls some method for changing the (x, y) positions, then subclass that to create VBranch and HBranch? Refactor these methods so that there is less duplicated code.

Ex. 21 — Use the same approach for rewriting SoundBranch and ScaleBranch so that there is less duplicated code.

Ex. 22 — (Advanced) Investigate the Java notion of a **interface**. Can you come up with a LLBranch interface that all our branches (Branch, VBranch, HBranch, SoundBranch, and ScaleBranch) might implement so as to reduce the duplication of code? You might also investigate the *design pattern* called "*Visitor*." Can you use that to make tree traversals more common?

Ex. 23 — Trace out insertInOrder and how it walks through an example tree in order to insert a new piece of data.

Ex. 24 — Trace out the right calls to insertInOrder for a set of 8 words that result (a) in an unbalanced tree with all words down the right branch, (b) in an unbalanced tree with all words down the left branch, and (c) a balanced tree.

Ex. 25 — (Advanced) Write the method balance() for a generic binary search tree that produces a balanced tree.

Ex. 26 — Write addFirst() and addLast() for LLNode so that all our linked lists can add to the front or end.

12 Circular Linked Lists and Graphs: Lists and Trees That Loop

Chapter Learning Objectives

Lists can loop—a latter node can have as its next point to an earlier node. We use a *circular linked list* sometimes to create circular lists, as when you are representing the cells in an animation, such as in the Nintendo vide game *Mario Brothers*.

Trees can also have loops, while children of different subtrees can be linked together. We call those kinds of trees *graphs*.

The computer science goals for this chapter are:

- To create linked lists that have loops in them, and how to avoid the dangerous parts of it.
- To explore the use of graphs, and how to traverse them.

The media learning goals for this chapter are:

- To create a looping cell animation, as used in older video games.

12.1 Making Cell Animation with Circular Linked Lists

The older reader may recall Nintendo's *Super Mario Brothers* (Figure 12.1). The Mario Brothers characters seemed to run and jump under the control of the user in exploring a virtual world. As Mario and Luigi "ran," their arms and legs seemed to move as they moved. The style of animation being used in those style games is called *cell animation*.

In a cell animation, characters are represented by a series of still images. In one image, the right leg might be raised and in front of the body. In the next image, the right leg might be on the ground. In a following image, the left leg might be raised ahead of the body, and so on. By rapidly showing different of these images, in sequence, the illusion of moving body parts is created. By moving where the images are displayed, the illusion is

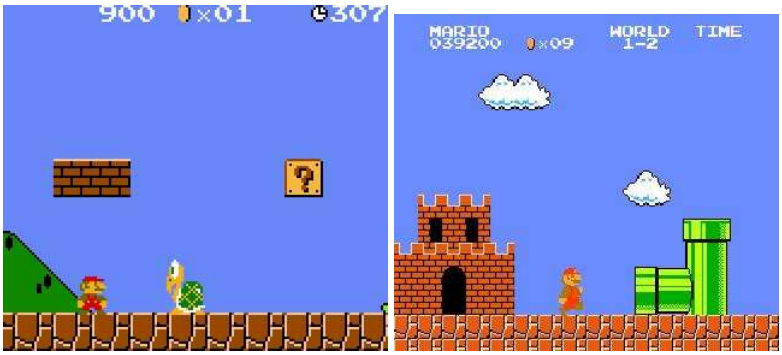

Figure 12.1: Scenes from Super Mario Brothers

gal1-rightface.jpg gal1-right2.jpg gal1-right1.jpg

Figure 12.2: Three images to be used in a cell animation

created that the moving body parts are actually driving the character. In the end, the character seems to run.

Let's create a version of cell animation. The wildebeests in *The Lion King* and the villagers in *The Hunchback of Notre Dame* are not examples of cell animation. In those cases, the body parts did move and were controlled at a fine level of detail. However, a cell animation *could* have been used to represent the characters whose positions are specified by a simulation. It is a particularly easy mechanism to be used in your own animations. Cell animations were invented for use on lower-powered processors (like the early Nintendo video games), so if you were to do an animation on a computer with little power (e.g., perhaps a cellphone), then cell animation would be a reasonable choice.

In your MediaSources folder on the CD, you will find some pictures of one of our daughter's dolls. These pictures are positioned (as best we could) to represent different positions in walking (Figure 12.2). We took the pictures against a blue background so that they could be used with chromakey.

We can arrange these images in a sequence to give the appearance of

Figure 12.3: A sequence of images arranged to give the appearance of walking

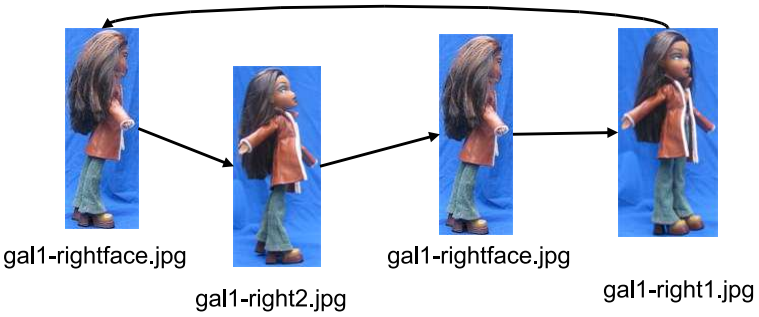

Figure 12.4: A circular linked list of images

walking, were they to be displayed one right after the other (Figure 12.3). These images are particularly stiff and give more of the impression of Frankenstein's monster walking—hopefully the point is made. Imagine these pictures in a flipbook, so that if you flipped the pages quickly, the images would seem to move.

One structure for arranging these images in the right order for display in a cell animation is a *circular linked list*. A circular linked list has at least one node (typically, the last node) whose next refers to a node earlier in the list (often, the first node). By arranging a series of picture nodes in a circular linked list gives us a simple way of defining the sequence of images for a cell animation (Figure 12.4).

A circular linked list is really useful for modeling lots of real things in the world. There are many things that contain loops: electrical circuits, pipe systems, maps of roads (e.g., there's always more than one way to go between two spots). The tricky aspect of a circular linked list is *never* to try to traverse the circular linked list to "the end," that is, where next is **null**. In a circular linked list, there is no **null** references.

Here's what we'll execute to create a walking doll (Figure 12.5):

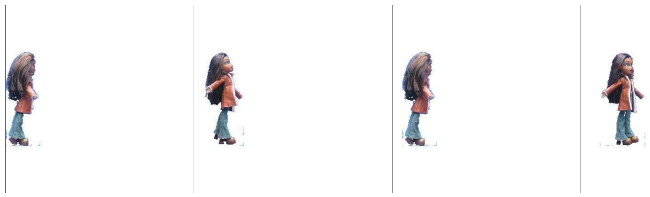

Figure 12.5: Frames of the walking doll

```
> WalkingDoll gal = new WalkingDoll(); gal.setUp();
> gal.steps(10);
```

How it works: To make our WalkingDoll class work, we keep track of a current node in the circular linked list and where the (x, y) position should be. To take a step, we display the current node's picture, then set the current equal to its next and update the position instance variables. Now, when the next step comes along, we will be displaying a new picture.

Program Example #99

Example Java Code: **WalkingDoll**

```
public class WalkingDoll {

  /**
   * Which character node position are we at?
   **/
  public CharNode current;

  /**
   * Starting position for new walking.
   **/
  public CharNode start;

  /**
   * Position for the character
   **/
  public int x, y;

  public int getX() {return x;}
  public int getY() {return y;}
  public void setLoc(int nux, int nuy){x=nux; y=nuy;}

  /**
   * FrameSequence for the display
   **/
  FrameSequence frames;
 /**
```

```
   * We'll do the list setup in the constructor
   **/
  public WalkingDoll(){
    Picture p = null; // For loading up images

    p = new Picture(FileChooser.getMediaPath("gal1-rightface.jpg"));
    start = new CharNode(p);
    p = new Picture(FileChooser.getMediaPath("gal1-right2.jpg"));
    CharNode rightfoot = new CharNode(p);
    p = new Picture(FileChooser.getMediaPath("gal1-rightface.jpg"));
    CharNode center = new CharNode(p);
    p = new Picture(FileChooser.getMediaPath("gal1-right1.jpg"));
    CharNode leftfoot = new CharNode(p);
    start.setNext(rightfoot); rightfoot.setNext(center);
    center.setNext(leftfoot);
    // Now the scary one
    leftfoot.setNext(start);

    frames = new FrameSequence("D:/Temp/");
  }

 /**
   * Setup to display walking left to right
   **/
  public void setUp(){
    x = 0; // Left side
    y = 300; // 300 pixels down
    frames.show();
    this.start();
  }
 /**
   * Start a walking sequence
   **/
  public void start() {
    current = start;
    this.draw();
  }

  /**
   * Draw the current character
   **/
  public void draw() {
    Picture bg = new Picture(400,400);
    Turtle pen = new Turtle(bg);
    pen.setPenDown(false); pen.moveTo(x,y);
    current.drawWith(pen);
    frames.addFrame(bg);
  }
 /**
   * Draw the next step
```

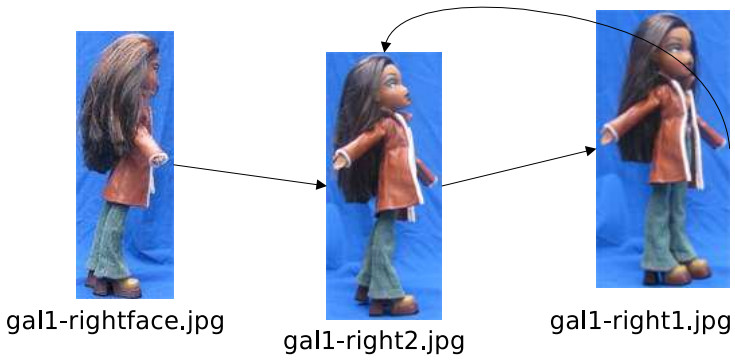

Figure 12.6: A partial circular linked list

```
   **/
  public void step(){
    current = (CharNode) current.getNext();
    x=x+10; // We'll try this
    this.draw();
  }

  /**
   * Draw a few steps
   **/
  public void steps(int num){
    for (int i=0; i < num; i++) {this.step();}}
}
```

While this works, the walking doll looks terrible. Like we said, it looks like Frankenstein's monster. We could fix this problem with better images. We might also remove the image where the legs come together between steps. We can model this by a circular linked list where the loop doesn't go all the way back to the beginning (Figure 12.6). The list starts with a single, standing image, then loops just on the movement of the legs.

12.2 Generalizing a Circular Linked List

Let's create a class like LLNode that makes it easy to create circular linked lists. The trick is never to look for **null**. This simple version simply refuses to do the things that would normally require a traversal to the **null** at the end of the list—no last and no remove.

```
> CharNode ch = new CharNode(new Picture(20,20));
> ch.last()
Don't try to find last() from a circular list!
```

```
CharNode with picture: Picture, filename null height 20 width 20
> ch.remove(new CharNode(new Picture(20,20)))
Very dangerous to try to remove a node from this list!
```

Example Java Code: **CharNode, a class for representing characters in cell animations** *Program Example #100*

```
/*
 * CharNode is a class representing a drawn picture
 * that is one in a sequence of Pictures to
 * use for a given character.  Don't ever try to traverse this one!
 **/
public class CharNode extends LLNode {
  /**
   * The picture I'm associated with
   **/
  public Picture myPict;

  /*
   * Make me with this picture
   * @param pict the Picture I'm associated with
   **/
  public CharNode(Picture pict){
    super(); // Call superclass constructor
    myPict = pict;
  }
 /**
   * Don't try to remove() from a circular list!
   **/
    public void remove(LLNode node){
      System.out.println("Very dangerous to try to remove a node from this list!");
    }

    /**
     * Don't try to get the last() from a circular list!
     **/

    public LLNode last() {
      System.out.println("Don't try to find last() from a circular list!");
      return this;
    }

  /**
   * Method to return a string with information
   * about this node. A NON-recursive one.
   */
  public String toString()
```

```
  {
    return "CharNode with picture: "+myPict;
  }

 /*
   * Use the given turtle to draw oneself
   * @param pen the Turtle to draw with
   **/
  public void drawWith(Turtle pen){
    // Assume that we're at the lower-left corner
    pen.setHeading(0); pen.forward(myPict.getHeight());
    Picture bg = pen.getPicture();
    myPict.bluescreen(bg,pen.getXPos(),pen.getYPos());
  }
}
```

How it works: While CharNode works, it works by taking the easy way out. The methods last(), remove(), and toString in LLNode involve traversing the whole list until next is **null**. CharNode simply prevents those methods from executing, by overriding them and displaying error messages.

There are better ways of implementing circular linked lists. How can we traverse a circular linked list without going on infinitely, looking for a end to a circle? There are several ways to do it—here are a couple:

- We could add another instance variable, a boolean named visited. As we visit a node, we mark it **true**. When we traverse the list, we mark each node that we print or whatever by setting visited to **true**. Then, rather than looking for next equal to **null**, we look for visited equal to **true**. When that's true, we've looped around and can stop. We need a reset method, too, that sets all visited flags to **false** (and keeps going until it finds a visited flag that is already **false**).

- We could have *two* next links in each node. One points to the next node created, and the other points to the next node to be traversed when displaying the cells. When we want to traverse all nodes (or add() or remove()), we use the first next. When we want to draw, we use the second next.

12.3 Graphs: Trees with Loops

In the previous sections, we have shown that there are some uses for linked lists with loops in them. How about trees? Is it useful to have nodes that link to previous nodes, e.g., children that point to their grandparents in the tree? With that kind of data structure, we can model all kinds of interest things that appear in the world.

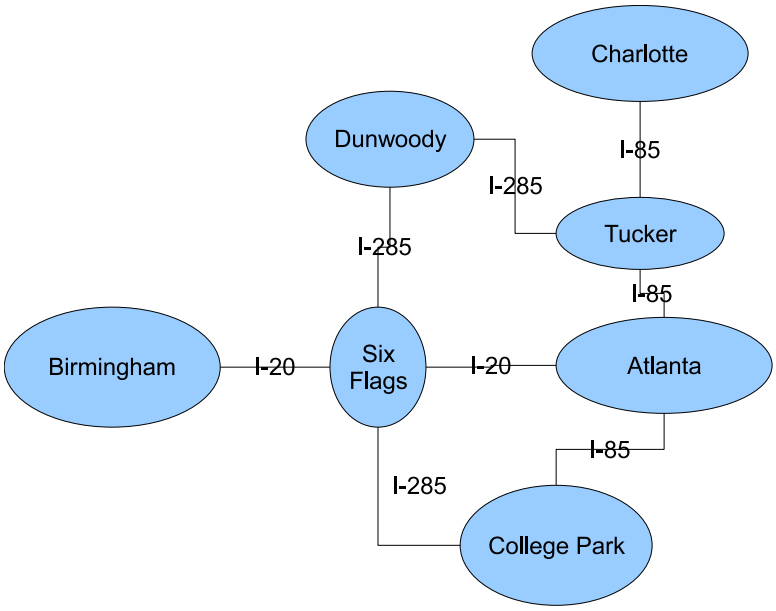

Figure 12.7: A map as a graph

We call these general structures where loops (or *cycles*) are allowed, *graph*s. A graph is a series of points or *vertices* connected with lines or *edges*. In some graphs, there is a directionality to the line or edge—node1 points to node3, but not vice-versa. We call those graphs a *directed* graph. Without that directionality, we call the graph *undirected*.

From this perspective, a tree is an unusual kind of graph. It's a graph without cycles. A tree is a kind of an *acyclic* graph.

Graphs are useful to model structures in the real world that have loops in them.

- Think about modeling a human circulatory system. There are clearly cycles in this graph—your blood doesn't flow to the end of your body and then out your fingers and toes. Your blood cycles back to the heart.

- A subway system is another example of a graph that has cycles. Each station is a vertex. Subway lines between stations are edges. Clearly there are cycles—on most subway systems, it's possible to go out one way and come back another way, or to find more than one way to get from one place to another.

- A map is another kind of graph (Figure 12.7). Cities (or even intersections or exits, depending on the detail you want) are vertices, and

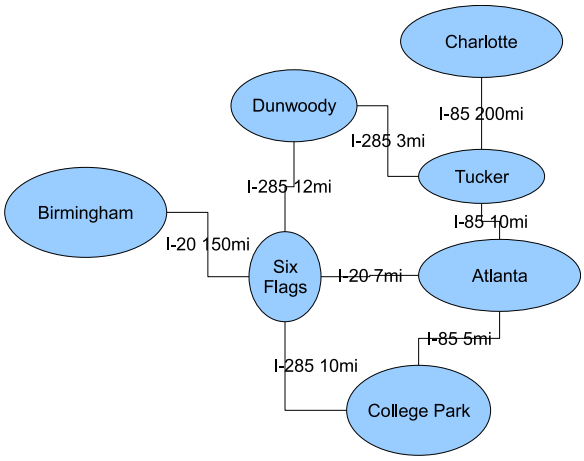

Figure 12.8: Apply weights to a graph—distances on a map

roads are edges. A map is a good example of a graph that has *costs* associated with edges. For many uses of maps, you care about the distance between any two vertices—that can be the cost of the edge (Figure 12.8).

Traversing graphs (doing something to every node) is particularly hard to do. As you can imagine from these examples, each node or vertex can actually be associated with a number of edges, not just one (as in a linked list) or two (as in binary tree). This means that a traversal has to make sure that every vertex is included, which may involve traveling down every ege.

The strategies for traversing graphs are similar to the strategies for traversing circular linked lists. We can add a visited flag to tell us whether or not we've visited a vertex. Then we can travel down every edge until we are sure that every node has visited equal to **true**. We can also keep a separate linked list of all the nodes so that we can check each node, regardless of how it's connected up into the graph.

A powerful tool for traversing a graph is to create a *spanning tree*. A spanning tree is the same graph (i.e., includes all the same vertices) without cycles. Once you have a spanning tree, you can visit all nodes using standard tree traversal techniques—you don't have to deal with the cycles.

One approach to computing a spanning tree is to use a *greedy algorithm*. A greedy algorithm, when having to make a choice (say, between which edge to follow from a given vertex) takes the shortest or easiest paths. That's being "greedy." It turns out that a greedy algorithm for creating a spanning tree on a graph actually results in a *minimal spanning tree*—a spanning tree that covers the least ground (has the lowest total cost).

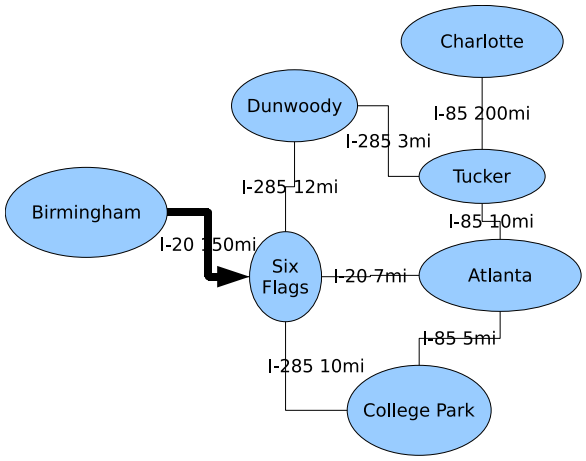

Figure 12.9: Traversing a graph to create a spanning tree

Let's imagine that something bad has happened in the United States—an invasion or an outbreak of an epidemic disease. In Birmingham on our map (Figure 12.7, there are troops or a vaccine. How do we visit all the cities on the map as quickly as possible, traveling the shortest path as possible. What we want is a minimal spanning tree.

The first step is obvious. We have to travel from Birmingham to Six Flags (Figure 12.9). From Six Flags we have several choices. We add Atlanta because it's the cheapest (lowest cost, shortest) path out of Six Flags (Figure 12.10). From Atlanta, we move to College Park as the next cheapest edge (Figure 12.11). We then have a problem. The only untraversed link out of College Park goes to Six Flags, where we've already been. We now *backtrack*, revisiting an earlier node to see if there are more paths from there. We backtrack to Atlanta where we do have a next-cheapest link (after the one to College Park) up to Tucker (Figure 12.12). From Tucker, we add the link to Dunwoody since it's obviously the cheapest (Figure 12.13). Dunwoody has no untraversed nodes (since we can't add Six Flags back in), so we backtrack again to Tucker, and then finish our minimal spanning tree at Charlotte (Figure 12.14).

You might be wondering how the algorithm figures out to which node to backtrack. It's pretty easy—it's another use for *stack*s. Each node, as it is visited, is pushed onto the stack. If you can't find another edge to follow from the node you're currently at, you pop off the top node from the stack, then see if there are more edges that need exploring from that node. You keep going until the stack is empty. The stack being empty is actually when you know that the algorithm is done.

Ex. 27 — Implement the circular linked list where the loop doesn't go all

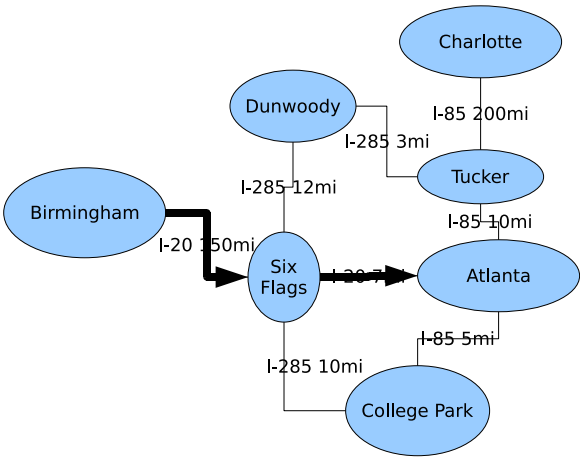

Figure 12.10: Choosing the cheapest path out of Six Flags

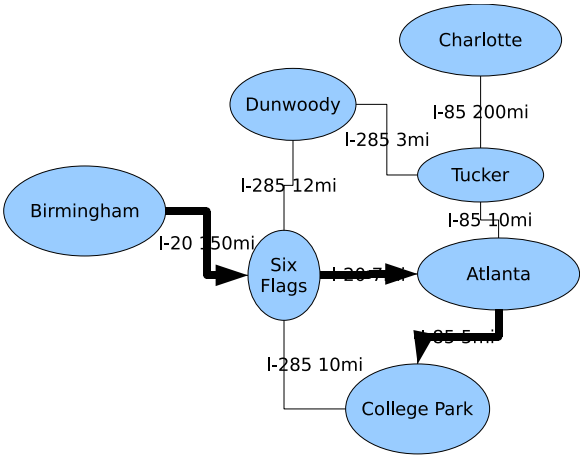

Figure 12.11: Going to College Park

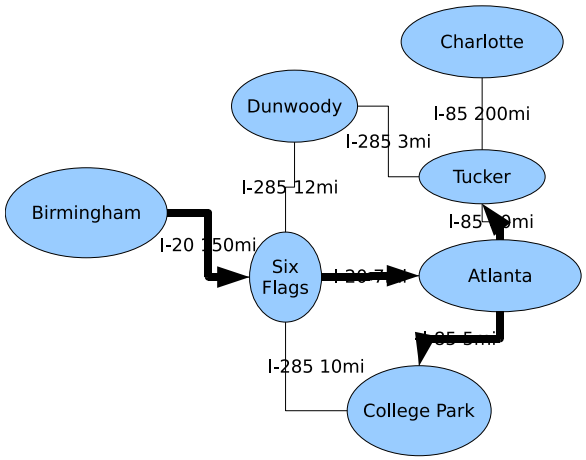

Figure 12.12: Backtracking to avoid re-visiting Six Flags

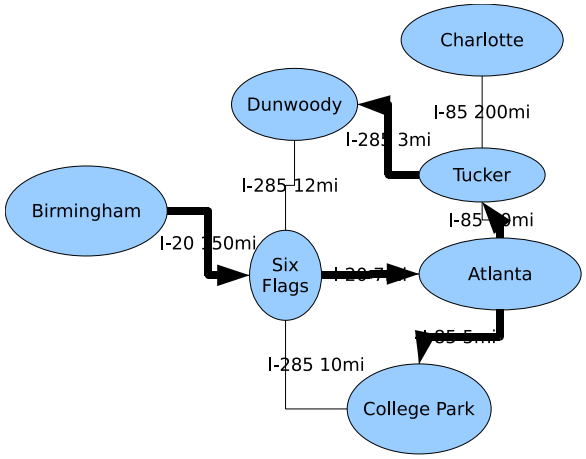

Figure 12.13: Adding Dunwoody, the obviously cheaper path

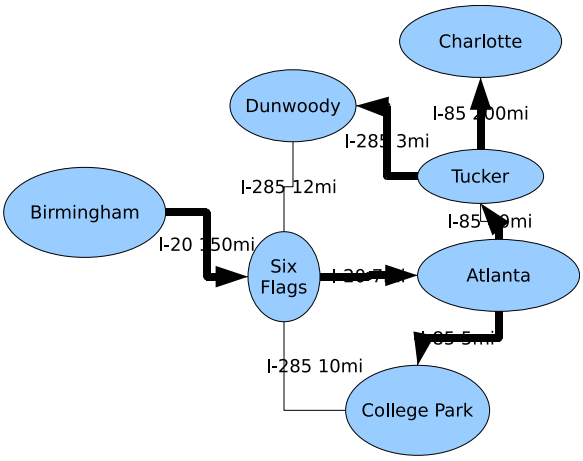

Figure 12.14: Finishing up in Charlotte

the way back to the front of the loop.

Ex. 28 — Implement walkBackwards for WalkingDoll class, so that the x position goes right to left, and the order of images swaps.

Ex. 29 — Implement walkToLeft for WalkingDoll class, where the images are flipped and x position goes right-to-left.

Ex. 30 — Implement a better CharacterNode class that uses one of the strategies described in this method to allow us to traverse a circular linked list without simply blocking dangerous methods.

13 User Interface Structures

Chapter Learning Objectives

We are all familiar with the basic pieces of a *graphical user interface (GUI)*: windows, menus, lists, buttons, scrollbars, and the like. As programmers, we can see that these elements are actually constructed using the lists and trees that we've seen in previous chapters. A window contains *panes* that in turn contain components such as *buttons* and *lists*. It's all a hierarchy, as might be represented by a tree. Different *layout managers* are essentially rendering the interface component tree via different traversals.

The computer science goals for this chapter are:

- To learn to construct graphical user interfaces using the *Swing* Java library.
- To recognize the structure of a user interface as a tree, and the role of a layout manager as a renderer.
- To use Swing components to construct media tools.
- To run Java programs from a command line.

The media learning goals for this chapter are:

- To understand how the interfaces for the applications that media developers use are constructed.
- To use interface components to interact with media.

13.1 A Toolkit for Building User Interfaces

Graphical user interfaces (GUIs) have many different kinds of pieces of them. A modern GUI has buttons (of different kinds, including radio buttons, check boxes, pushbuttons), text areas (with or without scroll bars), lists for making selections (some containing text, others with graphics), horizontal and vertical lines separating sections (or *panes*), images, and so on. Programmers typically use libraries for user interfaces. (These libraries are sometimes also called *toolkit*s.) These libraries provide the components, which the programmers can simply reuse.

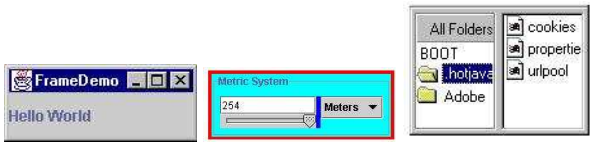

Figure 13.1: Examples of Swing components: JFrame, JPanel, and JSplitPane

The first toolkit for Java GUIs was call the *Abstract Window Toolkit* (AWT). The AWT provided containers for structuring the components, such as a Frame which was a main window with title and border, a Panel for grouping components, and a Canvas for creating custom components (in case you, as the programmer, really did want to build GUI components for yourself). Components that you would put into these containers included a Label (text that was only displayed, not editable), a Button, a TextField for entry and display of text, a TextArea entry and display of multiple lines of text, a List for selecting one or more items from a displayed list, and a Choice for selecting a selection from a drop down list, like a menu.

AWT had many problems. Users did not like the look of AWT user interfaces. AWT made all user interfaces look the same on all platforms (e.g., Microsoft Windows, Apple Macintosh, Linux), as opposed to looking like the windows on *your* platform. AWT was hard to program and fairly inflexible. Still, AWT is available in Java and sometimes (rarely) will be the right toolkit for a given program.

Sun released a new GUI toolkit called *Swing* which was available as a library named javax.swing. Swing replaced many of AWT's components, and provided a structure for more flexible and usable user interface. A Swing main window is called a JFrame (instead of a Frame), a group of components within a JFrame is put in a JPanel, and a button is JButton. Swing provided new components like a JTree for representing hierarchical structures, JSplitPane for have two groups of parallel components, and JTable which knows how to display tabular data. (Examples of some of these are in Figure 13.1.) Swing lets the programmer specify how the windows should look, e.g., like Windows, Mac, or other styles.

Building the simplest possible Swing user interface

Here are the steps for simply creating a window with a piece of text in it.

- First, you create the window. The main window is an instance of JFrame. You pass in the desired title to the constructor when you create the instance.

```
JFrame frame = new JFrame("FrameDemo");
```

- Next, you add components to the *content pane*. The content pane is the part of the window that holds other pieces of the user interface—the middle of the window, as opposed to the title bar or the close box. For this example, we will create a simple text label (a instance of JLabel) that will hold some text, then put that into the window.

  When you add a component into a container, you can tell it *where* you want the component to be. We are just going to put our text in the center of the window for now. This is going to become more important later in the chapter. We will explain BorderLayout, then.

  ```
  JLabel label = new JLabel("Hello World");
  frame.getContentPane().add(label, BorderLayout.CENTER);
  ```

- Now, we need to tell Java that we are done putting components into the window (at least for now). We tell Java to pack the window and figure out the minimal size for displaying on the screen.

  ```
  frame.pack(); // as big as needs to be to display contents
  ```

- Now, we're ready to display the window.

  ```
  frame.setVisible(true);  // display the frame
  ```

When you use Swing to create windows in your programs, you have to decide how to think about and structure your user interface. There are at least three ways to do it.

- Your first option is to think about your application object *as a kind of* JFrame. You create your application class as a subclass (**extends**) of JFrame. That is probably the easiest way to do it.

- Or, you can think about your application object as something that *owns* or *has* a JFrame. In that case, you typically have an instance variable that will hold the instance of JFrame, and you create that instance in the constructor method of your application object.

- Or, you can make your application object as a kind of JPanel that will simply get put into a JFrame in some other part of your program. For example, you might build a StartApplication class whose constructor method constructs your application object and inserts it into a JFrame, and your main method might create the StartApplication object. The advantage of building your object around a JPanel instead of a JFrame is that a JPanel gives you more flexibility. It can be put into a window, or an applet (a running Java program that runs inside of a web page in a web browser, using the class JApplet), or even as part of a larger application.

We are going to stick with the first option for now. We are going to aim for simplicity rather than flexibility right now.

13.2 Rendering of User Interfaces

In this section, we build a very simple user interface. We see how a user interface is a tree, and explore how to render that tree in different ways.

Building a Simple User Interface

Let's build the simplest possible user interface, using the same pattern that we saw before: Making a JFrame and sticking a JLabel in it. Notice that there's more code here, but it is commented out right now.

Program Example #101

Example Java Code: **A Simple GUItree class**

```
/**
 * A GUI that has various components in it, to demonstrate
 * UI components and layout managers (rendering)
 **/
import javax.swing.*; // Need this to reach Swing components

public class GUItree extends JFrame {

  public GUItree(){
    super("GUI Tree Example");

    /* Put in a panel with a label in it */
    JPanel panel1 = new JPanel();
    this.getContentPane().add(panel1);
    JLabel label = new JLabel("This is panel 1!");
    panel1.add(label);

    //NOTICE THAT THIS IS COMMENTED OUT!
    /* Put in another panel with two buttons in it
    JPanel panel2 = new JPanel();
    this.getContentPane().add(panel2);
    JButton button1 = new JButton("Make a sound");
    panel2.add(button1);
    JButton button2 = new JButton("Make a picture");
    panel2.add(button2);*/

    this.pack();
    this.setVisible(true);
  }
}
```

* * *

Figure 13.2: Simplest Possible GUI

How it works: Our class GUItree is a subclass of JFrame, meaning that creating a GUItree instance creates a window. In our constructor, we explicitly call **super**("GUI tree example") in order to ask the class JFrame to create a window with the title "GUI tree example." We then create a panel JPanel panel1, and add it into the window's content pane. We create a label saying "This is panel 1!" and put the label into the pane. We commented out a bunch of code, then we pack and make visible the window.

Computer Science Idea: We're building a tree

It might seem backward that we add the panel to the tree, *and then* add the label to the panel. Shouldn't we add the label to the panel, and then the panel to the tree? It really doesn't matter. We're constructing a set of relationships between parts of the GUI tree. The tree is used to make our window visible when we pack it and setVisible(**true**). When the parts got to the tree does not matter.

We run this program like this (in DrJava's interactions pane):

```
Welcome to DrJava.
> GUItree gt = new GUItree();
```

We hope you are wondering about that code we commented out. Let's remove the comment characters so that we can run the whole code.

Example Java Code: **Slightly more complex GUItree class** *Program Example #102*

```
public GUItree(){
   super("GUI Tree Example");

   /* Put in a panel with a label in it */
   JPanel panel1 = new JPanel();
```

```
    this.getContentPane().add(panel1);
    JLabel label = new JLabel("This is panel 1!");
    panel1.add(label);

    /* Put in another panel with two buttons in it */
    JPanel panel2 = new JPanel();
    this.getContentPane().add(panel2);
    JButton button1 = new JButton("Make a sound");
    panel2.add(button1);
    JButton button2 = new JButton("Make a picture");
    panel2.add(button2);

    this.pack();
    this.setVisible(true);
  }
```

How it works: This second version simply continues on from where the last one left off. A second panel is created and added to the frame's content pane. Two buttons are created and added into the panel.

We run this version the same way. What we see might be surprising (Figure 13.3). Where did the first panel and its label "This is panel 1!" go?

Figure 13.3: The slightly more complex GUItree, with two panes

Let's build yet another version of our simple user interface. In this version, we construct the *exact* same components in the exact same way. However, we use a *layout manager* that will arrange the window in particular way when we *render* the user interface.

Program Example #103

Example Java Code: **A Flowed GUItree**

```
/**
 * A GUI that has various components in it, to demonstrate
 * UI components and layout managers (rendering)
 **/
import javax.swing.*; // Need this to reach Swing components
import java.awt.*; // Need this to reach FlowLayout
```

Figure 13.4: Our GUItree, using a Flowed Layout Manager

```
public class GUItreeFlowed extends JFrame {

  public GUItreeFlowed(){
    super("GUI Tree Flowed Example");

    this.getContentPane().setLayout(new FlowLayout());
    /* Put in a panel with a label in it */
    JPanel panel1 = new JPanel();
    this.getContentPane().add(panel1);
    JLabel label = new JLabel("This is panel 1!");
    panel1.add(label);

    /* Put in another panel with two buttons in it */
    JPanel panel2 = new JPanel();
    this.getContentPane().add(panel2);
    JButton button1 = new JButton("Make a sound");
    panel2.add(button1);
     JButton button2 = new JButton("Make a picture");
     panel2.add(button2);

      this.pack();
    this.setVisible(true);
  }

}
```

We can see both panels in this version (Figure 13.4) because of the line:

```
this.getContentPane().setLayout(new FlowLayout());
```

That line creates a new FlowLayout instance and assigns it as the layout manager (via setLayout() for the frame's content pane.

A layout manager defines how the window will be *rendered*—how it will be drawn on the screen, and how it will behave when the window is resized. In both of our last two examples, we were defining a *tree* as in Figure 13.5. A graphical user interface is a tree. The frame is the root of the tree, and it has a child of a content pane. (It has other children, too, like a title bar, but those will not be visible in our simple examples.) The content pane has two other children—each of the two panels. Those panels

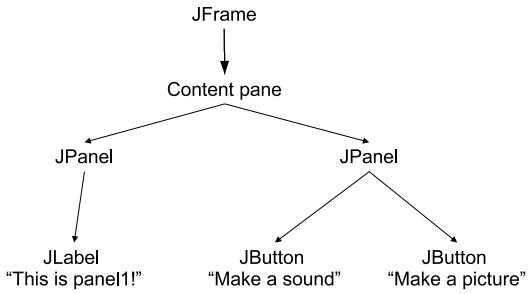

Figure 13.5: Diagram of components of GUI tree

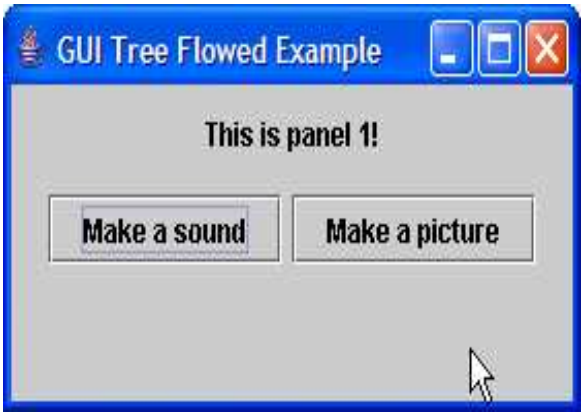

Figure 13.6: Resizing the Flowed GUItree

contain other children: a label or the two buttons.

The difference between the last two user interfaces, then, is not in the tree, but in how it is rendered. If you do not specify a layout manager, a default renderer is used—one that is not particularly easy to use, one that makes it particularly easy to overlay the same components (branches of the tree) on top of one another. A flowed layout manager makes it easy to lay out one element right after the other, as in Figure 13.4. When we resize the window (Figure 13.6), the components move in reasonable positions—that is also handled by the layout manager.

Java Swing Layout Managers: GUI tree renderers

A layout manager figures out how to lay out components within a window. It is possible to specify exactly what position each element should maintain in a window. There is a layout manager that allows us to specify the (x, y) position within the window where the component should be drawn, and the height and width of the component. The method for doing that is

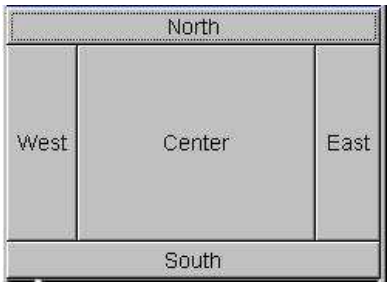

Figure 13.7: How a BorderLayout GUI is structured

setBounds(topLeftX,topLeftY,width,height). However, exact specification can lead to errors, and does not define what should happen if the window is resized.

The layout managers in Java Swing allow us to arrange components in a logical manner. The layout manager then positions and even sizes the components. The layout manager also handles resizing and repositioning the components (as necessary) when the window is resized. We will see that a layout manager can be assigned to a frame content pane *or* any panel. Thus, a panel may arrange its components differently than the overall frame (content pane) may arrange its components.

Different layout managers act on the exact same GUI component tree in different ways. Changing the layout manager will change in how the elements are positioned and sized. The same window will look differently when the window is resized, depending on the layout manager used.

FlowLayout

We have already seen the FlowLayout manager. A FlowLayout manager just places items one after the other, from left-to-right, with no extra space between the components. We can see that in Figure 13.4 and Figure 13.6. That may seem obvious—what else might you want? Turns out that there are *lots* of ways to layout and render a GUI tree.

BorderLayout

A popular layout manager is the BorderLayout. Using a BorderLayout manager, you specify the *directions* of where you want elements to be placed (Figure 13.7). Elements placed in the "north" appear at the top of the window, and elements placed in the "west" appear at the left. (You do not have to place elements in all the directions—as the programmer, you simply specify the general direction in which the elements should be placed.) A BorderLayout manager also resized elements, as well as placing them. It always gives the most space to the "center" element.

A BorderLayout manager lays out elements in a common user interface style. Certainly you have seen user interfaces like this. Word processing and image manipulation programs (as two examples) usually have a large work area with toolbars or menus or lists of options around the edges.

We can change our FlowLayout GUItree into a BorderLayout GUItree pretty simply. Instead of adding a new instance of FlowLayout as the layout manager for our content pane, we add an instance of BorderLayout.

```
this.getContentPane().setLayout(new BorderLayout());
```

One more change—as we add elements to our window, now, we specify *where* they are going to go. BorderLayout defines a set of constants, like BorderLayout.NORTH that allow us to specify where components should be added.

```
this.getContentPane().add(panel1,BorderLayout.NORTH);
```

Program Example #104

Example Java Code: **A BorderLayout GUItree**

```
/**
 * A GUI that has various components in it, to demonstrate
 * UI components and layout managers (rendering)
 **/
import javax.swing.*; // Need this to reach Swing components
import java.awt.*; // Need this to reach BorderLayout

public class GUItreeBordered extends JFrame {

  public GUItreeBordered(){
    super("GUI Tree Bordered Example");

    this.getContentPane().setLayout(new BorderLayout());
    /* Put in a panel with a label in it */
    JPanel panel1 = new JPanel();
    this.getContentPane().add(panel1,BorderLayout.NORTH);
    JLabel label = new JLabel("This is panel 1!");
    panel1.add(label);

    /* Put in another panel with two buttons in it */
    JPanel panel2 = new JPanel();
    this.getContentPane().add(panel2,BorderLayout.SOUTH);
    JButton button1 = new JButton("Make a sound");
    panel2.add(button1);
     JButton button2 = new JButton("Make a picture");
     panel2.add(button2);

      this.pack();
    this.setVisible(true);
```

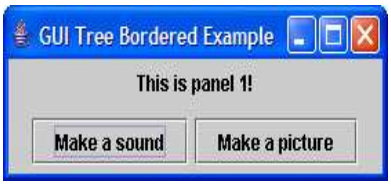

Figure 13.8: A BorderLayout GUItree

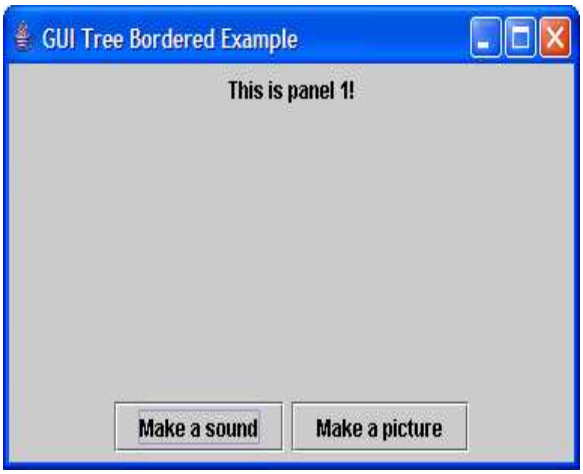

Figure 13.9: Resizing the BorderLayout GUItree

```
    }
}
```

Now, when we create our window, we see Figure 13.8. Since we placed panel1 in the NORTH and panel2 in the SOUTH, one is on top of the other. As we *resize* the window (Figure 13.9), those relationships remain. Compare this with the resizing of the FlowLayout GUItree (Figure 13.6)—the BorderLayout keeps the elements at the top and bottom, where the FlowLayout leaves the elements in the middle, one right after the other.

BoxedLayout

There are several other layout managers in Swing, that each form a tradeoff between flexibility and complexity. We have already seen that tradeoff, between the FlowLayout and BorderLayout managers. FlowLayout could hardly be easier to use, but it only stacks components one right after the other. A BorderLayout offers a bit more flexibility, in that the programmer can specify how things should be clustered (top or bottom, left or right). The tradeoff is that programmers must now specify where components

Figure 13.10: Example of a GridBag layout

should be clustered.

The layout managers are at different points in the complexity and flexibility spectrum. One layout manager is the default: None. It is perfectly acceptable for the programmer to specify where each component goes—that's a lot of flexibility, and a lot of complexity. Another layout manager is GridBag, which allows the programmer to specify a grid on which components are to be layed out (Figure 13.10. After the grid is specified, the programmer simply dumps them into the layout, as if into a "bag." That is a bit of complexity to set up the bag, which offers more flexibility than a BorderLayout. After that, it's as easy to use as a FlowLayout.

A more sophisticated (e.g., more complexity and more flexibility) layout manager is BoxLayout. A BoxLayout allows the user to group elements along a horizontal or vertical axis. The flexibility and complexity of BoxLayout is that the programmer can add in additional components that have no user interface function other than to constrain the layout. The programmer can create *rigid areas* that maintain a certain size and simply take up space, e.g., Box.createRigidArea(**new** Dimension(0,5)));. The programmer can also create *glue areas* that create constraints between components, keeping them "stuck" together, e.g., Box.createHorizontalGlue());.

Using a BoxLayout is a little different than the previous layout managers. Not only do we add the new instance of BoxLayout to the content pane, but we also pass the content pane as an input to the constructor for the BoxLayout. The reason for this is that the BoxLayout must be able to access the pane, as well as vice-versa. We also specify the dimension along which components are to be placed. Thus, we create the layout manager with:

```
this.getContentPane().setLayout(
    new BoxLayout(this.getContentPane(),
        BoxLayout.Y_AXIS));
```

In our example for our GUItree here, we do not use spaces or glue. The point is just to see how another layout manager renders the identical GUItree. The base rendering by the BoxLayout (Figure 13.11) looks pretty much like the BorderLayout rendering (Figure 13.8). The resizing behaves a bit differently—the BoxLayout keeps things organized along the Y-axis (Figure 13.12), but does not force the second panel to the bottom ("south")

of the window as does the BorderLayout (Figure 13.9).

Example Java Code: **A BoxLayout GUItree** *Program Example #105*

```
/**
 * A GUI that has various components in it, to demonstrate
 * UI components and layout managers (rendering)
 **/
import javax.swing.*; // Need this to reach Swing components

public class GUItreeBoxed extends JFrame {

  public GUItreeBoxed(){
    super("GUI Tree Boxed Example");

    this.getContentPane().setLayout(
        new BoxLayout(this.getContentPane(),
            BoxLayout.Y_AXIS));
    /* Put in a panel with a label in it */
    JPanel panel1 = new JPanel();
    this.getContentPane().add(panel1);
    JLabel label = new JLabel("This is panel 1!");
    panel1.add(label);

    /* Put in another panel with two buttons in it */
    JPanel panel2 = new JPanel();
    this.getContentPane().add(panel2);
    JButton button1 = new JButton("Make a sound");
    panel2.add(button1);
    JButton button2 = new JButton("Make a picture");
    panel2.add(button2);

    this.pack();
    this.setVisible(true);
  }
}
```

Which layout manager should be used and when?

Because each panel (JPanel) can have its own layout manager, and panels can be added within other panels, the programmer can actually use a variety of layout managers to lay out different pieces in different ways.

Some suggestions on when to use which layout managers:

- If you want to fit the most components into the least space, and you are okay with those components staying in the center of your pane

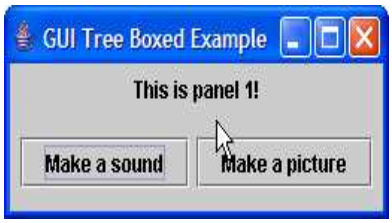

Figure 13.11: Our GUItree rendered by the BoxLayout

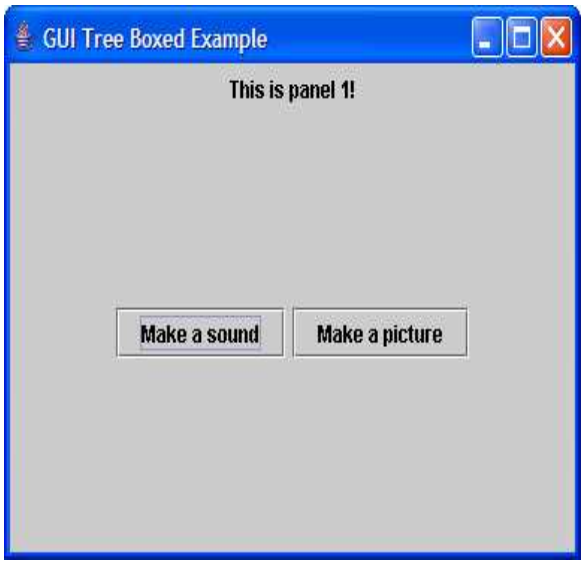

Figure 13.12: Resizing the BoxLayout GUItree

(or frame), then use FlowLayout.

- If you want to fit the components into the least space and want them *not* to be in the center, use a BorderLayout and put something in the window to use up the extra space in the center.
- If you are building an application where users need a large workspace (textual or graphical), the BorderLayout is designed just for that.
- If you want the elements to line up horizontally or vertically, use a BoxLayout.
- In the end, if you want the most control over what goes where, use the **null** layout.

Figure 13.13: Example of use of JScrollPane

13.3 A Cavalcade of Swing Components

This section is focused on introducing a bunch[1] of user interface components found in Swing. The information presented here will not be enough to write programs using these components. Rather, the goal here is to identify a few useful components and for some of the most useful, provide snippets of code in order to convey the general idea of how to use them. It is hard to get started using Swing components if you don't even know the names of the appropriate classes—that is what we are trying to deal with in this section. For detailed information on using any of these components, you should consult a reference on the Swing components, such as at Sun's official Java website[2].

- The class JScrollPane adds scrollbars to some other component, such as a text area or a graphic image (Figure 13.13). Adding a JScrollPane to a text area might look like this:

```
textArea = new JTextArea(5, 30);
JScrollPane scrollPane = new JScrollPane(textArea);
contentPane.add(scrollPane, BorderLayout.CENTER);
```

- In many user interfaces, different panels appear in the same window with tabs at the top for selecting between them, like tabs on folders in the same drawer. For example, Microsoft Office products often organize preferences or options in this way. The components for creating that structure in Swing is called a JTabbedPane (Figure 13.14).

- Groups of tool buttons are clustered in the JToolbar component (Figure 13.15).

- Sometimes, a program needs to prompt the user with a *dialog*, a small window that interrupts use of the normal window. The purpose is usually to alert the user to an important piece of news or ask the user for immediately needed information. The class for that kind of window in Swing is JOptionPane (Figure 13.16).

- In Microsoft Windows applications (more than in Linux or Macintosh), windows sometimes have internal windows. Those are constructed using the JInternalFrame class in Swing (Figure 13.17).

[1] A herd? A coven?

[2] As of this writing, Swing documentation can be found at `http://java.sun.com/javase/6/docs/technotes/guides/swing/`

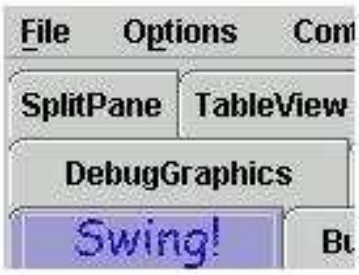

Figure 13.14: Example of a JTabbedPane

Figure 13.15: Example of JToolbar

Figure 13.16: An example of JOptionPane

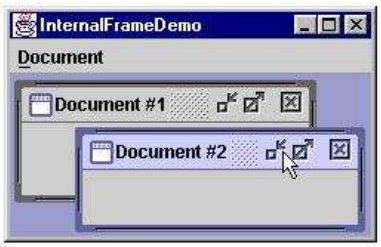

Figure 13.17: An example of JInternalFrame

Figure 13.18: An example of a JComboBox

Figure 13.19: An example of a JSlider

- One of the most flexible components in Swing is JList. It represents a list of items. These items can be text, or images, or both. A list can allow the user to select one item, or many items. There are a lot of options on JList.

- Offering the user a set of options where only one can be chosen can also be created using a *drop-down menu*. The Swing drop-down menu is implemented using a JComboBox (Figure 13.18).

```
// Setting up a combo box
JComboBox colorBox = new JComboBox(colorList);
// Getting the text in the selected item
String currColor = colorBox.getSelectedItem();
```

- Sometimes users need to input a value along a pre-defined set of values. A *slider* makes clear to the user what the valid range is for some input value. A JSlider provides an implementation of a slider. The below example creates the JSlider example in Figure 13.19.

```
// Create a slider with a range 100--1000
// Starting at 400
% **********BARB?  IS THAT RIGHT?!?
s = new JSlider(100, 1000, 400);
// Make small lines appear as tick marks
s.setPaintTicks(true);
// Where the spacing is 100 apart
s.setMajorTickSpacing(100);
s.getValue();   // get the current value from a slider
```

- Users like to get some signal that something is happening. A *progress bar* can show the computer making progress on some task that is otherwise invisible to the user. The example below (Figure 13.20) creates a horizontal progress bar using JProgressBar whose apparent value will change from zero to the length of some text, so that the programmer might update the progress bar as each character in the text is processed.

Figure 13.20: An example of a JProgressBar

Figure 13.21: An example of JColorChooser

```
progressBar = new JProgressBar(JProgressBar.HORIZONTAL,
        0, text.length());
```

- A *color chooser* is a dialog that allows the user to make a selection among a set of colors, then returns that color to the programmer. The class JColorChooser provides that dialog in Java. Unlike the other components discussed here, a JColorChooser is a separate window—it is not added to any pane to use it.

```
Color newColor = JColorChooser.showDialog(
                this, Pick a new background color ,
                this.getBackground());
```

- A common dialog used in programs is a *file chooser*. The Swing class JFileChooser provides a flexible mechanism for creating a file chooser (Figure 13.22). An instance of JFileChooser can be asked to only show files of a certain type, for example.

```
// create the file chooser
final JFileChooser fc = new JFileChooser();
// display the chooser as a dialog and get the return value
int returnVal = fc.showOpenDialog(frame);
// if the return value shows that the user selected a file
if (returnVal == JFileChooser.APPROVE_OPTION) {
        File file = fc.getSelectedFile();
}
```

There are several different ways of managing text in a user interface in Swing. Some of the choices to make (which determine which component

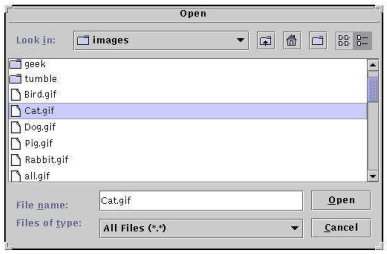

Figure 13.22: An example of JFileChooser

Figure 13.23: An example of a JTextField

to use) include how much text, whether the user should see the text, and whether the text will be input or just diplayed.

- If you simply want to display some text (without the user entering characters or changing the text), then the JLabel that we saw earlier would work fine.
- If you need to accept a line of text as input from the user, you can use JTextField (Figure 13.23). The below example sets up a text field of 40 characters, and gets the user input in a field into a String variable.

```
// To create the field
JTextField nameField = new JTextField(40);
// To get the text from the field
String name = nameField.getText();
```

- If your program needs to query the user for a password, you need to accept a line of text—but you do not want the text to be visible. You do not want a passerby to be able to read the password on the screen. The Swing component JPasswordField (Figure 13.24) serves this purpose.

```
// Set up the field to accept 8 characters
JPasswordField passField = new JPasswordField(8);
// Get the text from the field
String password = passField.getPassword();
```

- If you need to have the user type in several lines of text, then you need the component JTextArea (Figure 13.25).

```
// Set up the component, for 2 lines and 30 characters
JTextArea commentArea = new JTextArea(2,30);
```

Figure 13.24: An example of a JPasswordField

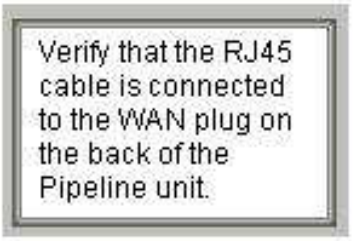

Figure 13.25: An example of a JTextArea

```
// Get the text out of it
String comment = commentArea.getText();
// Set the text to some String's value
commentArea.setText(comment);
```

13.4 Creating an Interactive User Interface

The interfaces we have created thus far have been static. The buttons do not *do* anything. While we could create some of components we just saw in the calvacade, we have not yet seen how to respond to user interactions with these components.

The key to creating interactive user interfaces is dealing with *event*s, *user interface events*. When a user does anything within a user interface, the computer generates an event object. A keystroke on the keyboard, a click of the mouse, or the click and drag on the thumb of a scrollbar are all events. A program can *listen* for these events—that is, provide a piece of code that will respond to a kind of event and take some action when that event occurs.

Creating a listener is like signing up for the mailing list of your favorite band. By signing up for the mailing list, you are saying to *someone* (in this analogy, the fan club of the band), "Please let me know if the band is doing anything interesting or coming to my town!" Creating a listener for a given event is saying to *something* (in the user interface case, the user interface event managing program), "I care about this particular event occurring—please let me know if it ever does."

Table 13.1 lists some of the most common user interface events and their listeners. Typically, listeners are associated with (or attached to) particular objects Thus, the listeners are triggered when the event *associated with that object* occurs. If you have five buttons in your user interface,

Action Type	*Listener Type*	*Example Event*
ActionEvent	ActionListener	A user clicks a button
AdjustmentEvent	AdjustmentListener	Move a scrollbar
FocusEvent	FocusListener	Tab into a text area
ItemEvent	ItemListener	Checkbox checked
KeyEvent	KeyListener	Key stroke
MouseEvent	MouseListener	Mouse button clicked
MouseEvent	MouseMotionListener	Mouse is moved
TextEvent	TextListener	A text is changed
WindowEvent	WindowListener	A window is closed

Table 13.1: A selection of events and their listeners

each will typically have their own ActionListener that waits for the user to click on the given button, and each will respond to a click on the associated button.

Notice that there is some ambiguity in these events. The same user interaction could correspond to many different events. Imagine moving a mouse over a button, then clicking on that button. Is that a MouseEvent or an ActionEvent? The answer is "Yes." You can have listeners for both kinds of events attached to the same button, and then both listeners will be triggered when the corresponding events occur.

In Java terms, a listener is actually an *interface*. It's not an actual class, and you cannot create listeners of them. An interface is the definition of a set of methods that perform some specific function or set of functions. A class that claims to implement a given interface is agreeing to a contract—the methods of that interface *must* be created in the class.

Swing provides a set of abstract classes called *adapter*s that agree to implement particular listeners. The adapter does provide all the necessary methods, but most of them are just empty—they do nothing at all. You as the programmer then create a subclass of the given adapter and override the methods as you need in order to respond to events appropriately. For example:

```
class MyMouseAdapter extends MouseAdapter
{
        /** Method to handle the click of a mouse */
        public void mouseClicked(MouseEvent e)
        {       }
}
```

If you think about all the buttons in a given interface, and having to create a new class to listen to each kind of event for each kind of button—you quickly find that there are a lot of classes to create. Java provides a particular structure to remove the necessity for all those separate classes. It's called *anonymous inner classes*. The idea is that you can create a sub-

class of a given class then instantiate it for use (as in a user interface) at that moment that you define the class (hence, "inner class," as it is created inside some other class). You do not even have to *name* the class—hence, "anonymous." In the below bit of code, we are adding an object to listen for a FocusEvent, and we create the class for that object right there—we define the methods focusGained and focusLost in the middle of the method call for addFocusListener.

```
b.addFocusListener(new FocusListener () {
public void focusGained (FocusEvent evt) {

}
public void focusLost(FocusEvent evt) {

}
});
```

Common Bug: Anonymous inner classes may not access method variables

Even though the anonymous inner classes are created *within* another class's method, the anonymous inner class does not have access to any variables in the method. That turns out to be non-intuitive. You create a variable, and two lines later (in the same method, seemingly) you want to access that variable—but you cannot. This requires some odd structures, like creating class variables (which the anonymous inner class *can* access) for access to objects that you would otherwise only reference locally within the method.

Making our GUItree interaction

After creating many variations on the basic GUItree, it seems reasonable to make that our first interactive interface. All we are really doing here is making the "Play" button play some sound, and the "Show" button shows some picture. Since we do not plan to do anything fancier with the button than let the user click it (e.g., we won't be playing the sound as soon as the mouse moves over the "Play" button), we will simply create an ActionListener anonymous inner class that will listen for the button's "action" – the typical click on a button.

Program Example #106

Example Java Code: **An interactive GUItree**

```
/**
 * A GUI that has various components in it, to demonstrate
```

```
 * UI components and layout managers (rendering).
 * Now with Interactivity!
 **/
// Need this to reach Swing components
import javax.swing.*;
// Need this to reach FlowLayout
import java.awt.*;
// Need this for listeners and events
import java.awt.event.*;

public class GUItreeInteractive extends JFrame {

  public GUItreeInteractive(){
    super("GUI Tree Interactive Example");

    this.getContentPane().setLayout(new FlowLayout());
    /* Put in a panel with a label in it */
    JPanel panel1 = new JPanel();
    this.getContentPane().add(panel1);
    JLabel label = new JLabel("This is panel 1!");
    panel1.add(label);

    /* Put in another panel with two buttons in it */
    JPanel panel2 = new JPanel();
    this.getContentPane().add(panel2);
    JButton button1 = new JButton("Make a sound");
    // Here's adding the listener
    button1.addActionListener(
      // Here's where we instantiate a new anonymous
      // inner class
      new ActionListener() {
        // Here's the method we're overriding
        public void actionPerformed(ActionEvent e) {
           Sound s = new Sound(
                FileChooser.getMediaPath("warble-h.wav"));
           s.play();
        }
      }
    );
    panel2.add(button1);

    /* Set up the second button */
    JButton button2 = new JButton("Make a picture");
    button2.addActionListener(
      // Here's the listener
      new ActionListener() {
        // Here's the method we're overriding
        public void actionPerformed(ActionEvent e) {
           Picture p = new Picture(
                FileChooser.getMediaPath("shops.jpg"));
```

```
            p.show();
          }
        }
      );
      panel2.add(button2);

      this.pack();
      this.setVisible(true);
    }

}
```

How it works: Most of the code is identical to our FlowedGUItree. The new parts are where we add a listener to each button, using the method addActionListener. The method takes as input a object which will do the listening, i.e., provide a method that will take an ActionEvent with the method actionPerformed. We *could* create a subclass of ActionListener, perhaps calling it ShowButtonActionListener and instantiate it here. That is what we are doing, but without the name. Our new subclass of ActionListener has only a single method in it, actionPerformed. That's where we do the showing and playing.

Creating a Rhythm-Creation Tool

Now we know enough about creating user interfaces that we can build some tool—a gadget that will allow some non-programming user to do things that we have only been able to do by programming Java up until now. In this section, we will create a tool to allow a user to specify a rhythm by creating copies of some sound, weaving and repeating the copies into a new sound (Figure 13.26).

Here are the parts of this window that we care about.

- There is a text field at the top of the window where we specify the filename of a sound to be inserted into our sound sequence. As a simplification, we will assume that all filenames are specified as base names, and they refer to files in our mediaPath.

- There are buttons for REPEAT and WEAVE that insert the sound into a sound sequence. These buttons take a numeric input—that's the field below the filename. When the REPEAT button is pressed, that number of copies of the sound are repeated at the end of the sound sequence. When the WEAVE button is pressed, that number of copies of the sound are woven into the sound sequence. We again use a simplification—we assume the weave is skip-one-insert-one.

Figure 13.26: A tool for generating rhythms

- Finally, at the bottom, there is a PLAY button to hear the sound sequence that we are creating.

We can already see that there are connections between the different parts of this user interface. For example, the repeat and the weave buttons need to be able to get the value from the count field. There are good ways for connecting objects, e.g., we could pass in the count field to the listener for the two buttons, so that it could ask the count field its value. To simplify the example, we will use an uglier but effective mechanism—we will simply create a new instance variable that will hold the value needed in more than one listener. That is not a good object-oriented solution. By creating the instance variable, we are saying, "All RhythmTool's should know their counts," which doesn't make obvious sense. At this point, though, we are more interested in understanding how to build the user interface than in how to design it well.

Let's build the RhythmTool class in pieces.

Example Java Code: **Start of RhythmTool**

Program Example #107

```
/**
 * A Rhythm-constructing tool
 **/
// Need this to reach Swing components
import javax.swing.*;
// Need this to reach FlowLayout
import java.awt.*;
```

```
// Need this for listeners and events
import java.awt.event.*;

public class RhythmTool extends JFrame {

  /* Base of sound that we're creating */
  public SoundElement root;
  /* Sound that we're creating to add in. */
  public SoundElement newSound;
  /* Declare these here so we can reach them inside listeners */
  private JTextField filename;
  private JTextField count;
  int num;
```

How it works: The **import** statements simply must be there, to access the appropriate libraries in Java. Here are the declarations for the instance fields (instance variables) that we need in our RhythmTool:

- The root variable will hold the sequence of sounds that we are creating, the linked list of SoundElement nodes.
- The newSound variable will hold the sound created from the filename entered. We will be using this variable to make a connection between the text field where the filename is entered to the buttons that will need it.
- The filename and count variables actually hold the text fields.
- The num variable holds the integer version of the number entered into the count text field (which we will originally fetch as a String).

Program Example #108

Example Java Code: **Starting the RhythmTool Window and Building the Filename Field**

```
public RhythmTool(){
    super("Rhythm Tool");

    root = new SoundElement(new Sound(1)); // Nearly empty sound
    newSound = new SoundElement(new Sound(1)); // Ditto

    // Layout for the window overall
    this.getContentPane().setLayout(new BorderLayout());

    /* First panel has new sound field */
    JPanel panel1 = new JPanel();
```

```
// Put panel one at the top
this.getContentPane().add(panel1,BorderLayout.NORTH);
// Create a space for entering a new sound filename
filename = new JTextField("soundfilename.wav");
filename.addActionListener(
  new ActionListener() {
  public void actionPerformed(ActionEvent e) {
    /* When hit return in filename field,
     * create a new sound with that name.
     * Printing is for debugging purposes.
     **/
    newSound = new SoundElement(
                    new Sound(
                     FileChooser.getMediaPath(filename.getText())));
    // For debugging purposes
    System.out.println("New sound from "+
                       FileChooser.getMediaPath(filename.getText()));
  }
}
);
panel1.add(filename);
```

How it works: All of the RhythmTool class content is in its constructor. When we create an instance of RhythmTool, the window opens and is usable. Besides setting up the title and the layout manager, the start of the constructor sets up a linked list of sound elements, using a one sample sound as the root of the list.

The text field for the filename is then set up. It is in a panel that is placed at the top (NORTH) of the window. Text fields can have ActionListeners, too. The "action" that triggers the ActionEvent is hitting ENTER (or RETURN) within the field. When that happens, we get the filename (filename.getText()), get the complete filename from getMediaPath, and make a sound from that file.

Common Bug: Declaring a variable makes it local

Notice that we do not *declare* the variable newSound. If we did, the variable would be local to the method. Rather, we want to access the instance variable declared at the top of the RhythmTool class.

Debugging Tip: Making the invisible visible

So that we know what's going on here, we print out a message to the con-

sole about the creation of the sound. Because the creation of the sound happens invisibly, getting some feedback can be helpful in knowing what's going on. If you REPEAT the sound and nothing happens to the sound sequence, we need to know if the repeat broke or if the sound was never created.

Program Example #109

Example Java Code: **Creating the Count Field in the RhythmTool**

```
/* Put in another panel with number field
    * and repeat & weave buttons */
   JPanel panel2 = new JPanel();
   // This layout is for the PANEL, not the WINDOW
   panel2.setLayout(new BorderLayout());
   // Add to MIDDLE of WINDOW
   this.getContentPane().add(panel2,BorderLayout.CENTER);
   // Add a field for arguments for Repeat and Weave
   count = new JTextField("10");
   num = 10; // Default value
   count.addActionListener(
     new ActionListener() {
     public void actionPerformed(ActionEvent e) {
       // Here's how we convert a string to a number
       num = Integer.parseInt(count.getText());
     }
   }
   );
   // Add to top of panel
   panel2.add(count,BorderLayout.NORTH);
```

How it works: Next, we create a panel that will hold the count field and the two buttons. We create a *separate* layout manager just for this pane. It will also be a BorderLayout, and the count field will go at the top (NORTH) of this panel.

The count text field holds a "10" to start. The user triggers the action of this field (by typing RETURN or ENTER). The action is to get the contents of the field as a String (count.getText()), then convert it to a number (Integer.parseInt). Again, we do not declare num because we want to access it elsewhere through the instance variable.

* * *

am
ple #110

Example Java Code: **RhythmTool's Buttons**

```
// Now do the Repeat button
    JButton button1 = new JButton("Repeat");
    button1.addActionListener(
      new ActionListener() {
        public void actionPerformed(ActionEvent e) {
          // Repeat the number of times specified
           root.repeatNext(newSound,num);
        }
      }
    );
    // Add to RIGHT of PANEL
    panel2.add(button1,BorderLayout.EAST);
 // Now do the Weave button
    JButton button2 = new JButton("Weave");
    button2.addActionListener(
      new ActionListener() {
        public void actionPerformed(ActionEvent e) {
          // We'll weave 10 copies in
          // every num times
           root.weave(newSound,10,num);
        }
      }
    );
    // Add to LEFT of PANEL
    panel2.add(button2,BorderLayout.WEST);
 /* Put in another panel with the Play button */
    JPanel panel3 = new JPanel();
    // Put in bottom of WINDOW
    this.getContentPane().add(panel3,BorderLayout.SOUTH);
    JButton button3 = new JButton("Play");
    button3.addActionListener(
      new ActionListener() {
        // If this gets triggered, play the composed sound
        public void actionPerformed(ActionEvent e) {
           root.playFromMeOn();
        }
      }
    );
     panel3.add(button3); // No layout manager here

    this.pack();
    this.setVisible(true);
  }

}
```

* * *

How it works: Creating the three buttons (REPEAT, WEAVE, and PLAY) are mostly repeated code. We create them and place them appropriate into their panels. (PLAY gets its own, new panel. Most of the effort here is setting up the window, not the actual execution of the tool. The actions for each of these buttons is a simple method call that we have used many times before. The variables for each call have been set up previously.

- REPEAT is simply root.repeatNext(newSound,num).
- WEAVE is simply root.weave(newSound,10,num).
- PLAY is simply root.playFromMeOn().

13.5 Running from the Command Line

What you might want to do here is to run your tool from the command line. You can do this pretty easily. We can even accept input from the command line, like the name of a filename to process.

Remember in our main methods, we specified String[] args as the input? That array of strings actually represents all the words in the command line when we execute our class from the command line, using the java command. Here is a test class for playing with this, which we see executed in Figure 13.27. Why did it end in an error? Because our args array was shorter, and we tried to reference words beyond the end of the line.

Program Example #111

Example Java Code: **Test program for String[] args**

```
public class TestStringArgs {
  public static void main(String [] args){
    System.out.println("0:"+args[0]);
    System.out.println("1:"+args[1]);
    System.out.println("2:"+args[2]);
  }
}
```

Imagine that we have a PictureTool class, rather than a RhythmTool, and we want to execute the picture with some file specified as input. We could create a class whose only job it is to run our picture tool with some input—a filename which we access as args[0]. Executing this tool on a filename looks like Figure 13.28.

* * *

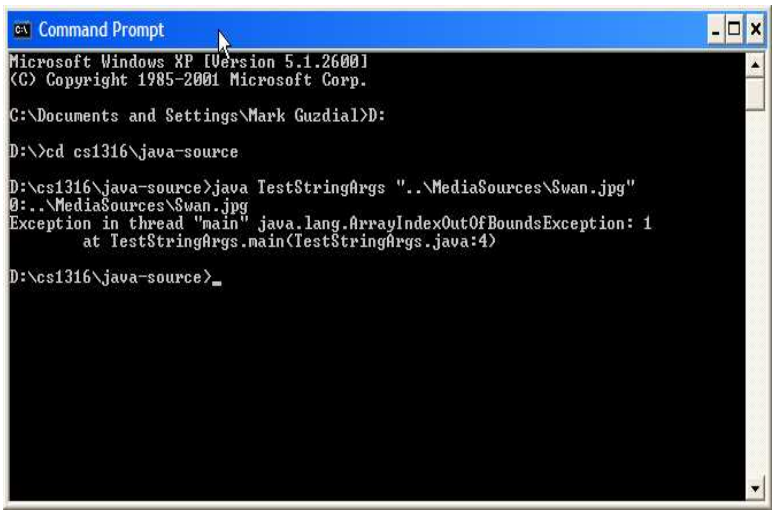

Figure 13.27: Exploring how String[] args works

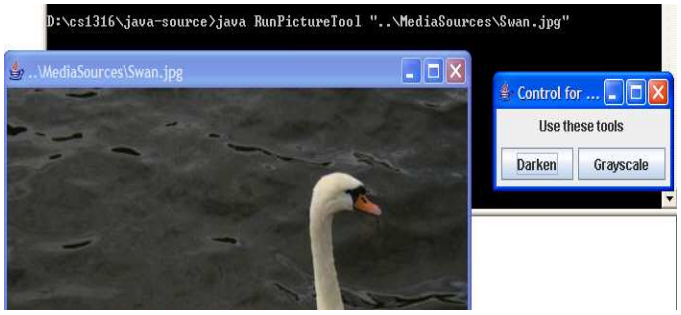

Figure 13.28: Executing PictureTool from the command line

am
ple #112

Example Java Code: **RunPictureTool**

```
public class RunPictureTool {
  public static void main (String[] args) {
    PictureTool pt = new PictureTool(args[0]);
  }
}
```

Ex. 31 — Modify the RhythmTool to allow the user to SAVE the newly created sound sequence.

Ex. 32 — Create another button for RhythmTool to create a new sequence—to clear out the current sequence.

Ex. 33 — Build a class named PictureTool whose constructor takes in a filename as input. You'll use it like this:

```
Welcome to DrJava.
> PictureTool pt = new PictureTool(FileChooser.getMediaPath(``swan.jpg''));
```

You should then (a) make a picture from that filename, (b) open the picture and tool buttons. Your tool buttons will manipulate the picture. It may look something like this:

You get to choose what tools that you provide, but there must be at least five:

- Provide two buttons for manipulating the color: Reduce red, increase red, make it grayscale, make it negative, darken, or lighten. Your choice. (You can provide more than two if you want.)
- Provide a tool that takes a numeric input and uses that input to manipulate the picture. Maybe it's a scaling tool and the input is amount to scale (2.0? 0.5?)? Maybe it's an amount to increase or decrease red?
- Provide a tool to do some kind of mirroring, either horizontal or vertical.
- One other tool of any kind you want. Flip? Red eye removal? Compose another figure scaled down into the bottom of the picture? Chromakey the picture into a jungle?
- Provide a text area for entering a filename, and a "Save" button that should save the resultant picture with the filename entered in the text area. (Suggestion: Only do this on *copies* of pictures that you want to manipulate!)

Every time that we click one of these tools, the picture should be manipulated and then the frame must be repainted! We want to see the change after clicking the tool. (Hint: Call frame.repaint() after manipulating the picture.)

In case you weren't aware—if you need to convert the String from a text field into a Double (with a floating point, like for scaling), you can use Double.parseDouble(String) like this:

```
> Double.parseDouble("3.45")
3.45
```

For extra credit, provide UNDO and REDO buttons. With these two buttons, you can always go back and forth when you don't like the change you made on the picture. You only need to support up to one level of "memory" of a previous event, so there's no need to use a dynamic data structure to implement this feature. Do note that the REDO button must be disabled until after you click the UNDO button.

Ex. 34 — Before writing the program you will create subfolders in your `MediaSources` folder with a number of topics ("flower", "motorcycle", "Britney Spears", etc.). You should have 10–12 topics with about 3–5 pictures for each and your directory structure should look like this (assuming your MediaSources folder is c:/cs1316/MediaSources):

- c:/cs1316/MediaSources/baseball/1.jpg
- c:/cs1316/MediaSources/baseball/2.jpg
- c:/cs1316/MediaSources/baseball/3.jpg
- c:/cs1316/MediaSources/speedy gonzalez/1.jpg
- c:/cs1316/MediaSources/speedy gonzalez/2.jpg
- ...

Notice that the topic is the subfolder and the images have a strict naming system (this will make them easier to choose).
You are now ready to start building a *collage generator*. Your GUI will allow users to choose 3–5 of these words or phrases (via a list, or selection of buttons, or typing them in, your choice but it must be in your user interface). Your generator then randomly selects pictures from those directories, randomly applies filters for them, and randomly creates a collage with those manipulated images. Finally, open it up as a picture.

Ex. 35 — Write a class TurtleEtchASketch[3] that will create a version of the classic "Etch-a-sketch" using a Turtle and present it visually using a GUI. You will need to have a Turtle draw on a Picture canvas, with directional buttons to control the movements of the Turtle.
Components you need to include:

- Directional buttons to control the Turtle.
  - –upButton and downButton to control vertical movement.

[3] Project created by Dawn Finney and Colin Potts.

–leftButton and rightButton to control horizontal movement.

- An input area (JTextArea and JTextField are good choices) to define how many pixels or steps the Turtle should move each time a directional button is clicked. (The default number of pixels should be 5).
- A submitButton for the input area.
- **Easy option:** Create 3 buttons to change the color of the line the Turtle draws or
- **Harder option:** Have a button to bring up a JColorChooser to change the color.
- Use a JLabel to hold the Picture that will serve as the background for the Turtle. The background Picture can be blank, but does not have to be.
- Be sure to have a shakeButton that clears the whole screen.

Ex. 36 — Build a class named MidiTool that will create a graphical user interface (GUI) for creating MIDI (music) sequences.
This GUI will have a string input area where the user can type in a sequence of letters. The letters will define a set of MIDI notes to define a *node*. Only the letters c,d,e,f,g,a, and b are allowed, presumed all in the third octave. Lowercase is an eighth note, uppercase is a quarter note. So cEdEgC would be c3 eighth, e3 quarter, d3 eighth, e3 quarter, g3 eighth, c3 quarter.
There should be buttons that allow users to create notes in a node, then weave nodes into a sequence:

- MakeNode converts the current string into a node.
- PlayNode plays the node.
- ClearSequence clears the current sequence.
- RepeatInSequence takes a number in a text area (“3”, for example) and repeats the currently made node that number of times onto the end of the sequence.
- WeaveInSequence weaves the currently made node into the sequence every-other node until the end of the sequence.
- PlaySequence plays the sequence.

Be sure to handle error conditions. What should happen if someone chooses to repeat or weave a node into a sequence when no node has been made? What should happen if illegal characters are entered into the string for a node? These are decisions you can make. A Java runtime error, however, is not an appropriate message to a user.
For extra credit, create a SaveSequence button that saves the sequence into a MIDI file.

Part IV

Simulations: Problem Solving with Data Structures

14 Using an Existing Simulation Package

We may put a chapter here that uses Greenfoot or Gridworld. The idea is to *use* a simulation package, before exploring how one is built and how to pull an animation out of one.

15 Introducing UML and Continuous Simulations

Chapter Learning Objectives

We're now starting on the third major theme of this book. The first two were programming media in Java and structuring media using dynamic structures (e.g., linked lists and trees). The third theme is simulations, and here's where we use all of the above to create our villagers and wildebeests.

The problem being addressed in this chapter is how to model dynamic situations, and then, how to simulate those models.

The computer science goals for this chapter are:

- To be able to use the basic terminology of simulations: Discrete event vs. continuous, resources, and queues.
- To describe linked lists as a *head* and a *tail* (or *rest*).
- To learn generalization and aggregation as two mechanisms for modelling with objects.
- To use UML class diagrams for describing the class structure of increasingly sophisticated object models.
- To implement a simple predator-prey simulation.
- To write numeric data to a file for later manipulation.

The media learning goals for this chapter are:

- To describe (and modify) behavior of agents in order to create different graphical simulations (like the Wildebeests and Villagers).
- To use spreadsheets (like Excel) for analyzing the results of graphical simulations.

15.1 Introducing Simulations

> A simulation is a representation of a system of objects in a real or fantasy world. The purpose of creating a computer simulation is to provide a framework in which to understand the simulated situation, for example, to understand the behavior of a waiting line, the workload of clerks, or the timeliness of service to customers. A computer simulation makes it possible to collect statistics about these situations, and to test out new ideas about their organization.

The above quote is by Adele Goldberg and Dave Robson from their 1989 book in which they introduced the programming language *Smalltalk* to the world [Goldberg and Robson, 1989]. Smalltalk is important for being the first language explicitly called "object-oriented," and it was the language in which the desktop user interface (overlapping windows, icons, menus, and a mouse pointer) was invented. And Smalltalk was invented, in part, in order to create *simulations*.

Simulations are representations of the world (models) that are executed (made to behave like things in the world). The idea of objects in Smalltalk were based on a programming language called *Simula*, which was entirely invented to build simulations. Object-oriented programming makes it easier to build simulations, because objects were designed to model real-world objects.

- In the real world, things *know* stuff and they *know how to do* stuff. We don't mean to anthropomorphize the world, but there is a sense in which real world objects *know* and *know how*. Blood cells *know* the oxygen that they carry, and they *know how* to pass it through to other cells through permeable membranes. Students know the courses that they want, and Registrars know the course catalog.

- Objects get things done by *asking* each other to do things, not by demanding or controlling other things. The important point is that there is an *interface* between objects that defines how they interact with each other. Blood cells don't force their oxygen into other cells. Students register for classes by requesting a seat from a registrar– it's not often that a student gets away with registering by placing themselves on a class roll.

- Objects decide what they share and what they don't share. The Registrar doesn't know what a student wants to enroll for, and the student won't get the class she wants until the desired course is shared with the Registrar.

Object-oriented programming was invented to make simulations easier, but not *just* to build simulations. Alan Kay, who was one of the key

thinkers behind Smalltalk and object-oriented programming, had the insight that simulations were a great way to think about *all* kinds of programs. A course registration system is actually a simulation of a model of how a campus works. A spreadsheet is a simulation of the physical paper books in which accountants would do their totals and account tracking.

There are two main kinds of simulations. Continuous simulations represent every moment of the simulated world. Most video games can be thought of as continuous simulations. Weather simulations and simulations of nuclear blasts tend to be continuous because you have to track everything at every moment. Discrete event simulations, on the other hand, do not represent *every* moment of time in a simulation.

Discrete event simulations only simulate the moments when something interesting happens. Discrete event simulations are often the most useful in professional situations. If you want to use a simulation of a factory floor, in order to determine the optimal number of machines and the layout of those machines, then you really don't care about simulating the product when it's in the stamping machine, cutter, or polisher. You only care about noting when material enters and leaves those machines–and having some way to measure how much the material was *probably* in the machine for. Similarly, if you wanted to simulate Napoleon's march to Russia (maybe to explore what would have happened if they'd taken a different route, or if the weather was 10 degrees warmer), you care about how many people marched each day, and consider some notion of how many might succumb to the cold each day. But you really don't need to simulate every foot-dragging, miserable moment–just the ones that really matter.

The real trick of a discrete event simulation, then, is to figure out when you should simulate–when something interesting should happen, so that you can jump right to those moments. We're going to find that there are several important parts of a discrete event simulation that will enable us to do that. For example, we will have an *event queue* that will keep track of what are the important points that we know about so-far, and when are they supposed to happen.

Discrete event simulations (and sometimes continuous simulations) tend to involve *resources*. Resources are what the active, working beings (or *agents*) in the simulation strive for. A resource might be a book in a library, or a teller in a bank, or a car at a rental agency. We say that some resources are *fixed*–there's only so much of it (like cars in a rental car), and no more is created even if more is needed. Other resources are *produced* and *consumed*, like jelly beans or chips (just keep crunching, we'll make more).

We can also think of resources as points of coordination in a simulation. Imagine that you are simulating a hospital where both doctors and patients are agents being simulated. You want to simulate that, during some procedure (say, an operation), both the doctor and patient have to be at the same place and can't do anything else until the procedure is done. In that case, the operating table might be the *coordinated resource*, and

when both the doctor and patient access that resource, they're both stuck until done.

If an agent can't get the resource it wants when it wants it, we say that the agent enters a *queue*. In the United Kingdom, people know that word well–in the United States, we simply call it "a line" and being in a queue is "getting in line." A queue is an ordered collection (that is, there is a first, and a second, and eventually, a last) where the first one into the line is the first one that comes out of the line (and the second one in is the second one out, and so on). It's a basic notion of "fairness." We sometimes call a queue a *FIFO list*–a list of items that are first-in-first-out. If an agent can't get the resource that she wants, she enters a queue waiting for more resource to be produced or for a resource to be returned by some other agent (if it's a fixed resource).

The interesting question of any simulation is *Is the model right?* Do the agents interact in the way that describes the real world correctly? Do the agents request the right resources in the right way? And then, how do we *implement* those models? To get started, let's build one model and simulate that model.

15.2 Our First Model and Simulation: Wolves and Deer

We are going to explore a few different kinds of continuous simulations in this chapter. We'll be using our Turtle class to represent individuals in our simulated worlds. The first simulation that we're going to build is a simulation of wolves chasing and eating deer (Figure 15.1). Wolves and deer is an instance of a common form of continuous simulation called *predator and prey* simulations.

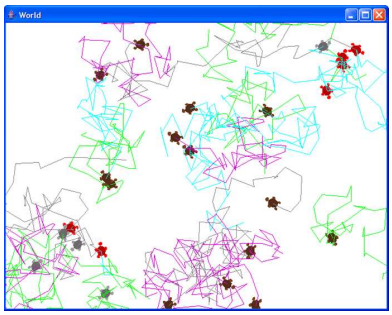

Figure 15.1: An execution of our wolves and deer simulation

The name of this class is WolfDeerSimulation. We can start an execution like this:

```
Welcome to DrJava.
```

```
> WolfDeerSimulation wds = new WolfDeerSimulation()
> wds.run()
>>> Timestep: 0
Wolves left: 5
Deer left: 20
>>> Timestep: 1
Wolves left: 5
Deer left: 20
<SIGH!> A deer died...
>>> Timestep: 2
Wolves left: 5
Deer left: 19
>>> Timestep: 3
Wolves left: 5
Deer left: 19
<SIGH!> A deer died...
>>> Timestep: 4
Wolves left: 5
Deer left: 18
```

What we see is Figure 15.1. Wolves (in gray) move around and (occasionally) catch deer (in brown), at which point the deer turn red to indicate their death (depicted above with a <SIGH!>). This is a very simple model, but we're going to grow it further in the book.

WolfDeerSimulation is a continuous simulation. Each moment in time is simulated. There are no resources in this simulation. It is an example of a predator-prey simulation, which is a common real world (ecological) situation. In these kinds of simulations, there are parameters (variables or rules) to change to explore under what conditions predators and prey survive and in what numbers. You can see in this example that we are showing how many wolves and deer survive at each *time step*–that is, after each moment in the simulation's notion of time. (It's up to the modeler to decide if a moment stands for a nanosecond or a hundred years.)

Modelling the Wolves and Deer

Simulations will require many more classes than the past projects that we have done. Figure 15.2 describes the relationships in the Wolves and Deer simulation.

- We are going to use our Turtle class to model the wolves and deer. The class Wolf and the class Deer are subclasses of the class turtle. Simulation agents will be told to act() once per timestep–it's in that method wolves and deer will do whatever they are told to do. Deer instances also know how to die(), and Wolf instances also know how to find the closest deer (in order to eat it).
- We will use the handy-dandy LLNode class in order to create a linked list of agents (which are in our case kinds of Turtle) through the

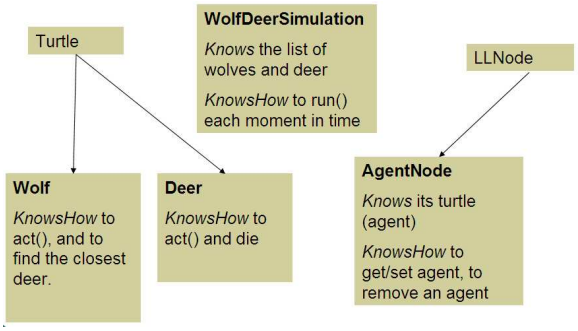

Figure 15.2: The class relationships in the Wolves and Deer simulation

AgentNode class. The AgentNode class knows how to get and set its agents (Turtle instances) and to remove an agent from the list. Removing an agent from the list of agents is a little more complicated than simply removing a node from a linked list–the first thing we have to do is to find the node containing the input turtle and *then* remove the node.

- The overall WolfDeerSimulation keeps track of all the wolves and deer. It also knows how to run() the simulation. To run a simulation has a few basic parts:
  - The world must be set up and populated with wolves and deer.
  - In a loop (often called a *event loop* or *time loop*), time is incremented.
  - At each moment in time, each agent in the world is told to do whatever it needs to do (e.g., act()). Then the world display is updated.

Now, while that may seem complex, the reality is that Figure 15.2 doesn't capture all the relationships between the different classes in this simulation. For example, how does the WolfDeerSimulation keep track of the wolves and deer? You can probably figure out that it must have instance variables that hold AgentNode instances. But this figure doesn't reflect the entire *object model*. Let's talk about how to describe object models using a software industry standard that captures more of the details in how the classes in the simulation interact.

15.3 Modelling in Objects

As we said at the beginning of this chapter, object-oriented programming was invented to make simulations easier to build. The individual objects

are clearly connected to real-world objects, but there are also techniques for thinking about how classes and objects relate to one another that helps to capture how objects in the real world relate to one another. Using these techniques is referred to as *modelling* in terms of objects, or *object modelling*. We call the process of studying a situation and coming up with the appropriate object-oriented model *object-oriented analysis*.

Computer Science Idea: The relationship between objects is meant to model reality

When an object modeler sets up relationships between objects, she is making a statement about how she sees the real world works.

Two of the kinds of object relationships that we use in modelling are *generalization-specialization* and *aggregation*.

- When we create a *generalization-specialization* relationship, we are saying that one class "is a kind of" the other class. Generalization-specialization relationships occur in the real world. Think of muscle and blood cells as specializations of the general concept of a cell. This relationship is typically implemented as a *subclass-superclass relationship*. When we created the Student class by extending Person, we were saying that a student is a kind of person. A student is a *specialization* of a person. A person is a *generalization* of a student.

- Another common object relationship is *aggregation*. This is simply the idea that objects exist within one another. Within you are organs (heart, lungs, brain), and each of these are individualized cells. If we were to model these organs and cells as objects, we would have objects inside of other objects.

  Expert object modelers make a further distinction in aggregation between what we might call "*has-a*" relationship (sometimes called an *association relationship* or simply a *reference relationship*), in contrast with an aggregation where the parts make up the whole. Imagine that you were modelling a human being. You could model the human as two arms and hands, two legs and feet, a torso, and neck and head. In that case, all those parts make up the whole of a human–that's the latter kind of aggregation. On the other hand, if you were modelling the cardiovascular system, you might model just hearts and lungs for each human in your simulation–even though, we know that humans have more than just hearts and lungs in them. A human "has-a" heart and two lungs, but that's not all that they are. Modelers sometimes call that an *association relationship*–humans *is associated with* a heart object and two lung objects.

We can describe many kinds of object models with just these two kinds of relationships. But if we were to spell out sentences like "A Person and a Student have a generalization-specialization relationship" for every relationship in our models, they would go on for pages. Just look at what we wrote in the last section for the wolves and deer simulation, and that wasn't even all the relationships in that model!

Object modelers use graphical notations like the *Unified Modelling Language* for describing their models. The Unified Modelling Language (*UML*) has several different kinds of diagrams in it, such as diagrams for describing the order of operations in different objects over time (a *collaboration diagram* or *sequence diagram*) or describing the different states (values of variables) that an object can be in during a particular process (a *state diagram*). The diagram that we're going to use is the *class diagram* that describes the relationships, methods, and fields in an object model.

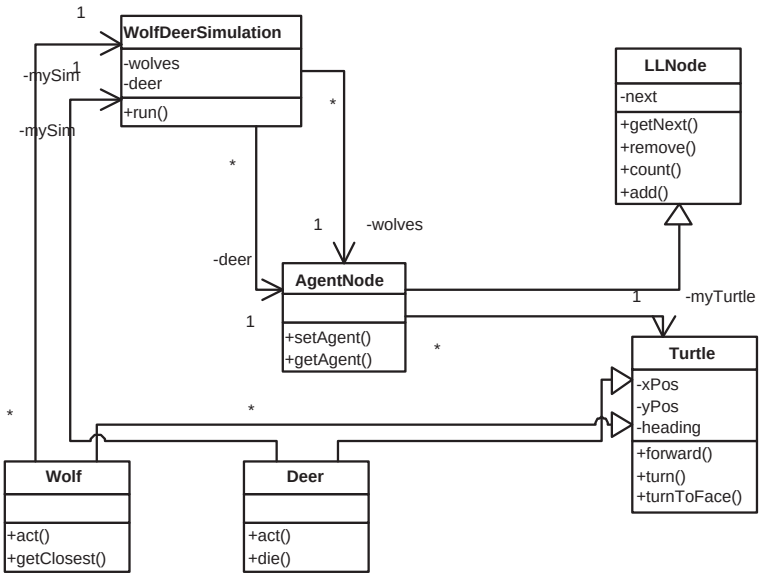

Figure 15.3: A UML class diagram for the wolves and deer simulation

Figure 15.3 is a UML class diagram describing the classes in our wolves and deer simulation. There are lots of relationships described in this diagram. While it may look complex, there really are two only kinds of relationships going on here, and the rest are things that you already know a lot about.

The boxes are the individual UML classes (Figure 15.4). They are split into thirds. The top part lists the name of the class. The middle part lists the instance variables (also called *fields*) for this class. Besides the name,

sometimes the type of the variable is also listed (e.g., what kind of objects are stored in this variable?). The symbols in front of the names of the fields indicate the accessibility. A '+' indicates a public field, a '-' indicates a private field, and a '#' indicates a protected field. Finally, the bottom lists the methods or operations for this class. Like the fields, the accessibility is also indicated with a prefix on the method name.

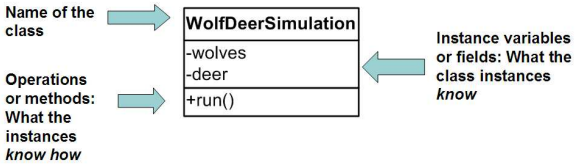

Figure 15.4: One UML class

Some fields may not appear in the class box. Instead, they might appear as a name on a reference relationship. Figure 15.5 pulls out just the reference relationship from the overall diagram. Reference relationships ("has-a" relationship) have open arrow points, and they indicate that one kind of object contains a reference to the other object. In this example, we see that the class Wolf contains a reference to its WolfDeerSimulation. The name of this reference is mySim. This means that Wolf contains an additional field named mySim that doesn't have to appear in the class box. You're also seeing a "1" on one end of the reference link, and a "*" on the other end. This means that each Wolf references exactly one WolfDeerSimulation, but many (that's what "*" means – anywhere from 0 to infinity) wolves might be in one simulation. The arrowhead could actually be on both sides. If a WolfDeerSimulation referenced at least one Wolf, then the arrows would go both way.

At this point, you might be wondering, "Huh? I thought that there were wolves in this simulation?" There are other, but not direction from the simulation object to the wolf object. There are other objects in there. Follow the lines in Figure 15.3. WolfDeerSimulation contains an AgentNode named wolves. (See that "1" in there? Exactly one direct reference.) AgentNode contains a turtle named myTurtle. That's how a simulation contains wolves and deer.

Because, odd as it seems, this diagram claims that wolves and deer are kinds of turtles (Figure 15.6). The lines that have closed arrows at their ends are depicting generalization-specialization (*gen-spec*) relationships. The arrow points toward the generalization (superclass). Figure 15.6 says that deers are kinds of turtles. (Are you imagining small turtles with antlers pasted onto their heads? Or maybe with gray or brown fur glued onto the shells?) This is what is sometimes called *implementation inheritance*–we want Deer instances to behave like Turtles in terms of movement

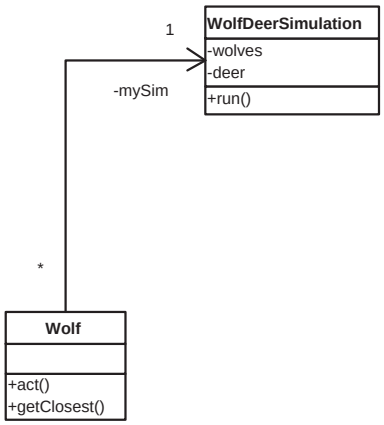

Figure 15.5: A Reference Relationship

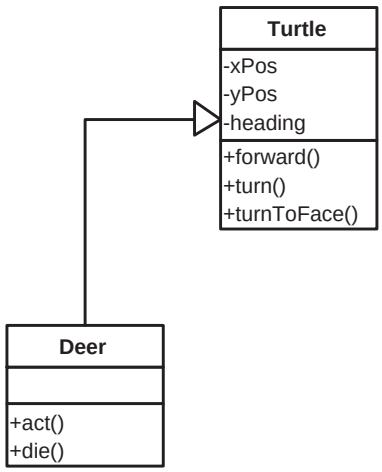

Figure 15.6: A Gen-Spec (Generalization-Specialization) relationship

and appearance. But from a modelling perspective, it's pretty silly to say that a deer is a kind of turtle. We'll fix that later.

15.4 Implementing the Simulation Class

The whole WolfDeerSimulation can be found at Program Program Example #153 (page 470). Let's walk through the key parts here.

```
public class WolfDeerSimulation {
```

```
/* Linked lists for tracking wolves and deer */
private AgentNode wolves;
private AgentNode deer;

/** Accessors for wolves and deer */
public AgentNode getWolves(){return wolves;}
public AgentNode getDeer(){return deer;}
```

Why do we declare our wolves and deer references to be **private**? Because we don't want them to be access except through accessors that we provide. Just imagine some rogue hacker wolf, gaining access to the positions of *all* the deer! No, of course, that's not the idea. But access to data is an important part of the model. Wolves *can* get deer's positions–by seeing them! If that's the only way that wolves find deer in the real world, then we should make sure that that's the only way it happens in our model, and we'll hide information that the wolf shouldn't have access to. If all the data were public, then a programmer might accidentally access data that one part of the model isn't supposed to access.

Now let's start looking at the run() method.

```
public void run()
 {
   World w = new World();
   w.setAutoRepaint(false);

   // Start the lists
   wolves = new AgentNode();
   deer = new AgentNode();

   // create some deer
   int numDeer = 20;
   for (int i = 0; i < numDeer; i++)
   {
     deer.add(new AgentNode(new Deer(w,this)));
   }

   // create some wolves
   int numWolves = 5;
   for (int i = 0; i < numWolves; i++)
   {
     wolves.add(new AgentNode(new Wolf(w,this)));
   }
```

The first part of this method is saying that we don't want the World doesn't update (repaint) until we tell it to. Within a single time step, everything is supposed to be happening at the same moment, but we have to tell each agent to act() separately. We won't the World to update during each turtle (er, wolf and deer) movement. So we'll tell it to wait.

The rest of the example above is creating the wolves and deer lists. Notice that the deer variable references an AgentNode that is *empty*–there's no deer in there! Same for wolves. Then in the loops, we create each additional AgentNode with a Deer or a Wolf. Each Deer and Wolf takes as input the world w and the simulation **this**. The new AgentNodes get added to the respective linked lists.

Why the empty node at the front? This is actually a much more common linked list structure than the one that we've used up until now. Figure 15.7 describes what the structure looks like. This is sometimes called a *head-tail* or *head-rest* structure. What we're doing is setting up a node for wolves and deer to point at that does *not* itself contain a wolf or deer. Why? Recall our remove() code for removing a node from a list–it can't remove the first node in the list. How could it–we can't change what the variables wolves and deer point at within the method. If the nodes that wolves and deer reference actually contained a wolf and a deer, those would be invulnerable objects–they could never die and thus be removed from the list of living wolves or deer. The first node is immortal! Since that's probably a highly unusual situation to have immortal wolves and deer, we'll use a head-tail structure so that we can remove animals from our list.

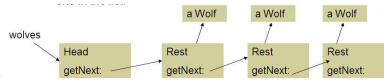

Figure 15.7: The structure of the wolves linked list

Here's the next part of the run() method, where we invite our wolves and deer act.

```
// declare a wolf and deer
Wolf currentWolf = null;
Deer currentDeer = null;
AgentNode currentNode = null;

// loop for a set number of timesteps (50 here)
for (int t = 0; t < 50; t++)
{
  // loop through all the wolves
  currentNode = (AgentNode) wolves.getNext();
  while (currentNode != null)
  {
    currentWolf = (Wolf) currentNode.getAgent();
    currentWolf.act();
    currentNode = (AgentNode) currentNode.getNext();
  }
  // loop through all the deer
  currentNode = (AgentNode) deer.getNext();
  while (currentNode != null)
```

```
    {
      currentDeer = (Deer) currentNode.getAgent();
      currentDeer.act();
      currentNode = (AgentNode) currentNode.getNext();
    }
```

What's going on in here is that, within a **for** loop that counts up to 50 time steps, we traverse the wolves and then deer linked lists, inviting each one to act(). But the code probably looks more complicated than that, because of the *casting* going on.

- currentNode = (AgentNode) wolves.getNext();–remember that AgentNode is a subclass of LLNode. getNext() returns an LLNode, so we have to cast it to an AgentNode to be able to do AgentNode-specific stuff, like getting at the agent.
- currentWolf = (Wolf) currentNode.getAgent();–remember that AgentNodes contain Turtles, but we need a Wolf to get it to act(). So, we have to cast again.

Same things are going on in the Deer part of the loop.

Finally, the end of the run() method in WolfDeerSimulation.

```
      // repaint the world to show the movement
      w.repaint();

      // Let's figure out where we stand...
      System.out.println(">>> Timestep: "+t);
      System.out.println("Wolves left: "+wolves.getNext().count());
      System.out.println("Deer left: "+deer.getNext().count());

      // Wait for one second
      //Thread.sleep(1000);
    }
  }
```

First, we tell the world "Everyone's had a chance to update! Show the world!" We then print the current statistics about the world–how many deer and wolves are left, by counting. Our count() method is very simple and doesn't understand about head-tail structures, so we'll call count() on the tail (the getNext()) to avoid counting the empty *head* as one wolf or deer. If you have a really fast computer and the world is updating faster than you can really see (one can dream), you might want to uncomment the line Thread.sleep(). That causes the execution to pause for 1000 milliseconds–a whole second, so that you can see the screen before it updates again.

15.5 Implementing a Wolf

The complete Wolf class can be found at Program Program Example #154 (page 473). Here's how it starts.

```
import java.awt.Color;
import java.util.Random;
import java.util.Iterator;

/**
 * Class that represents a wolf.   The wolf class
 * tracks all the living wolves with a linked list.
 *
 * @author Barb Ericson ericson@cc.gatech.edu
 */
public class Wolf extends Turtle
{
  /////////////// fields ////////////////////

    /** class constant for the color */
    private static final Color grey = new Color(153,153,153);
    /** class constant for probability of NOT turning */
    protected static final double PROB_OF_STAY = 1/10;
    /** class constant for top speed (max num steps can move in a timestep) */
    protected static final int maxSpeed = 60;

    /** My simulation */
    protected WolfDeerSimulation mySim;

    /** random number generator */
    protected static Random randNumGen = new Random();
```

There's a new term we've never seen here before: **final**. A **final** variable is one that can't actually ever vary–it's value is stuck right from the beginning. It's a *constant*. You never *have* to say **final**, but there are advantages to using it. Java can be more efficient in its use of memory and generate even a little faster code if you declare things that will never change **final**.

Making It Work Tip: Names of constants are capitalized

Java discourse rules say that you capitalize values that are **final**, that will never change, in order to highlight them and set them apart.

We're using **final** values here to set the value of the wolves and the probability that they will *not* turn in any given time step. We really only need one copy of these variables for the whole class (e.g., we don't need another copy of the color grey for each and every wolf), so we're declaring them **static**, too. We declare them **protected** because we might want to create new kinds of wolves (specializations of wolves) that will want to access these. Remember that **protected** fields can be accessed by the class

or any of its subclasses[1].

In the past, when we needed a random value, we simply accessed the method Math.random(). That method returns a **double** between 0 and 1 where all values are equally likely. That all numbers are "equally likely" is called a *uniform distribution*. That's a problem because relatively few things are uniformly distributed. Think about heights in your room or in your school. Let's say that you have someone who is 6 foot 10 inches tall and someone else 4 foot 11 inches tall. Does that mean that there are just as many people 6-10 as there are 4-11, and 5-0, 5-1, 5-2, and so on? We know that that's not how heights work. Most of the people are near the average height, and only a few people are at the maximum or minimum. That's a *normal distribution*, so-named because it is so, well, *normal*!

Instances of the class Random know how to generate random values on a normal distribution, as well as on a uniform distribution. We'll see those methods later, but we'll get started creating instances of Random now to get ready for that.

The next part of Wolf are the constructors. The constructors for Wolf are fairly complicated. They have to match Turtle's constructors which have to do with things like ModelDisplay which is an **interface** that World obeys. We will also have them call init() in order to *initialize* the agent. Here's what they look like.

```
//////////////////////////////// Constructors ////////////////////////

  /**
   * Constructor that takes the model display (the original
   * position will be randomly assigned)
   * @param modelDisplayer thing that displays the model
   * @param mySim my simulation
   */
  public Wolf (ModelDisplay modelDisplayer, WolfDeerSimulation thisSim)
  {
    super(randNumGen.nextInt(modelDisplayer.getWidth()),
          randNumGen.nextInt(modelDisplayer.getHeight()),
          modelDisplayer);
    init(thisSim);
  }

  /** Constructor that takes the x and y and a model
   * display to draw it on
   * @param x the starting x position
   * @param y the starting y position
   * @param modelDisplayer the thing that displays the model
   * @param mySim my simulation
```

[1]In Java, protected fields can actually be accessed from any class in the same package. Did you notice us creating any new packages so far? No? Then by default, all the code we've created can access any protected field. Not particularly protected, so we don't use **protected** much.

```
   */
  public Wolf (int x, int y, ModelDisplay modelDisplayer,
               WolfDeerSimulation thisSim)
  {
    // let the parent constructor handle it
    super(x,y,modelDisplayer);
    init(thisSim);
  }
```

Initializing a Wolf is fairly simple.

```
 ////////////////// methods /////////////////////////////////////

  /**
   * Method to initialize the new wolf object
   */
  public void init(WolfDeerSimulation thisSim)
  {
    // set the color of this wolf
    setColor(grey);

    // turn some random direction
    this.turn(randNumGen.nextInt(360));

    // set my simulation
    mySim = thisSim;
  }
```

Here, we are setting the wolf's color to grey, making it point in some random direction, and setting its reference mySim back up to the simulation that was passed in via the constructor. The method nextInt on Random returns a random integer between 0 and one less than the number provided as input. So randNumGen.nextInt(360) then returns a random number between 0 and 359.

Next comes a very important method, especially if you are a wolf. How do we figure out if there's a deer near enough to eat?

```
public AgentNode getClosest(double distance,AgentNode list)
  {
    // get the head of the deer linked list
    AgentNode head = list;
    AgentNode curr = head;
    AgentNode closest = null;
    Deer thisDeer;
    double closestDistance = 0;
    double currDistance = 0;

    // loop through the linked list looking for the closest deer
    while (curr != null)
```

```
    {
      thisDeer = (Deer) curr.getAgent();
      currDistance = thisDeer.getDistance(
                   this.getXPos(),this.getYPos());
      if (currDistance < distance)
      {
        if (closest == null || currDistance < closestDistance)
        {
          closest = curr;
          closestDistance = currDistance;
        }
      }
      curr = (AgentNode) curr.getNext();
    }
    return closest;
  }
```

The method getClosest() searches through the given list to see if there's a deer-agent in the list that is within distance (the input parameter) of **this** wolf. Wolves can only see or hear or smell within some range or distance, according to our model. So, we'll look for the closest deer within the range. If the closest deer is outside the range, this method will just return **null**.

For the most part, this is just a traversal of the linked list. We walk the list of AgentNodes, and grab thisDeer out of the current node curr. We then compute the distance between thisDeer and this wolf's position (**this**.getXPos(), **this**.getYPos()). If the distance to this deer is within our range distance, then we consider if it's the closest. The two vertical bars (||) mean logical "or." If we have no closest deer yet (closest == **null**) or if this is closer than our current closest deer (currDistance < closestDistance), then we say that the current AgentNode is the closest, and that this currDistance is the new closestDistance. At the end, we return the closest AgentNode.

Now that we know how wolves will go about finding something to eat, we can see how they will actually behave when told to act().

```
  /**
   * Method to act during a time step
   * pick a random direction and move some random amount up to top speed
   */
  public void act()
  {

    // get the closest deer within some specified distance
    AgentNode closeDeer = getClosest(30,
                                (AgentNode) mySim.getDeer().getNext());

    if (closeDeer != null)
    {
      Deer thisDeer = (Deer) closeDeer.getAgent();
      this.moveTo(thisDeer.getXPos(),
```

```
                    thisDeer.getYPos());
        thisDeer.die();
      }
    else // if we can't eat, then move
      {

        // if the random number is > prob of NOT turning then turn
        if (randNumGen.nextFloat() > PROB_OF_STAY)
        {
          this.turn(randNumGen.nextInt(360));
        }

        // go forward some random amount
        forward(randNumGen.nextInt(maxSpeed));
      }
    }
```

Here's what our Wolf does:

- The very first thing a wolf does is to see if there's something to eat! It checks to see if there's a close deer within its sensing range (30). If there is, the wolf gets the deer out of the agent (via getAgent), move to the position of that deer, and eat the deer (tell it to die).
- If the wolf can't eat, it moves. It generates a random number (with nextFloat() which returns a uniform number between 0 and 1), and if that random number is greater than the probability of just keeping our current heading (PROB_OF_STAY), then we turn some random amount. We then move forward at some random value less than a wolf's maximum speed.

15.6 Implementing Deer

The Deer class is at Program Program
Example #155 (page 476). There's not much new in the declarations of Deer (e.g., we declare a **static final** value for brown instead of grey) or in the constructors. When Deer instances act(), they don't eat anything in this model, so they don't have to hunt for closest anything. Instead, they just run around randomly. Note that they don't even look for wolves and try to get away from them yet.

```
  /**
    * Method to act during a time step
    * pick a random direction and move some random amount up to top speed
    */
   public void act()
   {
     // if the random number is > prob of NOT turning then turn
     if (randNumGen.nextFloat() > PROB_OF_STAY)
     {
```

```
        this.turn(randNumGen.nextInt(360));
    }

    // go forward some random amount
    forward(randNumGen.nextInt(maxSpeed));
  }
```

The interesting thing that Deer instances do in contrast to Wolf instances is to die.

```
 /**
   * Method that handles when a deer dies
   */
  public void die()
  {
    // Leave a mark on the world where I died...
    this.setBodyColor(Color.red);

    // Remove me from the "live" list
    mySim.getDeer().remove(this);

    // ask the model display to remove this
    // Think of this as "ask the viewable world to remove this turtle"
    //this.getModelDisplay().remove(this);

    System.out.println("<SIGH!> A deer died...");
  }
```

When a Deer instance dies, we set its body color to Color.red. We then remove the deer from the list of living deer. We could, if we wished, remove the body of the dead deer from the screen, by removing the turtle from the list of turtle's in the world. That's what **this**.getModelDisplay().remove(**this**); does. Finally, we print the deer's obituary to the screen.

15.7 Implementing AgentNode

The full class AgentNode is at Program Program
Example #156 (page 479). As we know from our earlier use of LLNode, there's not much to AgentNode–it's fairly easy to create a linked list of agents (Turtle instances) by subclassing LLNode.

The interesting part of AgentNode is the removal method that takes a Deer as input and removes the AgentNode that contains the input Deer instance.

```
 /**
   * Remove the node where this turtle is found.
   **/
  public void remove(Turtle myTurtle) {
    // Assume we're calling on the head
    AgentNode head = this;
```

```
    AgentNode current = (AgentNode) this.getNext();

    while (current != null) {
      if (current.getAgent() == myTurtle)
      {// If found the turtle, remove that node
        head.remove(current);
      }

      current = (AgentNode) current.getNext();
    }
  }
```

In this method, we have a linked list traversal where we're looking for the node whose agent is the input Turtle–current.getAgent() == myTurtle. Once we find the right node, we call the normal linked list remove() on that node.

This is a generally useful method–it removes a node based on the *content* of the node. Could we add this method to LLNode? Do we have to subclass and create AgentNode in order to make this work? Actually we could create a general linked list class that could hold anything. There is a class named Object that is the superclass of everything–even if you don't say **extends**, you are implicitly subclassing Object in Java. If you had an instance variable that was declared Object, it could hold any kind of content: A Picture, a Turtle, a Student–anything.

15.8 Extending the Simulation

There are lots of things that we might change in the simulation. We might have wolves that are hungry sometimes and not hungry other times. We could have wolves chase deer, and have deer run from wolves. We'll implement these variations to see how we change simulations and implement different models. That is how people use simulations to answer questions. But to get answers, we need to do more than simply run the simulation and watch the pictures go by. We need to be able to get data out of it. We'll do that by generating files that can be read into Excel and analyzed, e.g., with graphs.

Making Hungry Wolves

Let's start out by creating a subclass of Wolf whose instances are sometimes hungry and sometimes satisfied. What's involved in making that happen? The whole class is at Program Program
Example #157 (page 481).

```
/**
 * A class that extends the Wolf to have a Hunger level.
 * Wolves only eat when they're hungry
 **/
```

```
public class HungryWolf extends Wolf {
  /**
   * Number of cycles before I'll eat again
   **/
  private int satisfied;

  /** class constant for number of turns before hungry */
  private static final int MAX_SATISFIED = 3;
```

Obviously, we need to subclass Wolf. We will also need to add another field, satisfied, that will model how hungry or satisfied the HungryWolf is. We will have a new constant that indicates just how satisfied the HungryWolf instance is.

Here's how we will model satisfaction or hunger. When a HungryWolf eats, we will set the satisfied state to the MAX_SATISFIED. But each time that a time step passes, we decrement the satisfied state–making the wolf less satisfied. The wolf will only eat, then, if the wolf's satisfaction drops below zero.

The constructors for HungryWolf look just like Wolf's, which is as they must be.

```
  /**
   * Constructor that takes the model display (the original
   * position will be randomly assigned)
   * @param modelDisplayer thing that displays the model
   * @param mySim my simulation
   */
  public HungryWolf (ModelDisplay modelDisplayer, WolfDeerSimulation thisSim)
  {
    super(modelDisplayer, thisSim);
  }

  /** Constructor that takes the x and y and a model
   * display to draw it on
   * @param x the starting x position
   * @param y the starting y position
   * @param modelDisplayer the thing that displays the model
   * @param mySim my simulation
   */
  public HungryWolf (int x, int y, ModelDisplay modelDisplayer,
                     WolfDeerSimulation thisSim)
  {
    // let the parent constructor handle it
    super(x,y,modelDisplayer,thisSim);
  }
```

The initialization method for HungryWolf does not do much, but nor does it need to. By simply calling upon its superclass, the HungryWolf only has to do what it must do as a specialization–start out satisfied.

```
  /**
```

```
   * Method to initialize the hungry wolf object
   */
  public void init(WolfDeerSimulation thisSim)
  {
    super.init(thisSim);

    satisfied = MAX_SATISFIED;
  }
```

How a HungryWolf acts must also change slightly compared with how a Wolf. The differences require us to rewrite act()–we can't simply inherit and specialize as we did with init().

```
 /**
   * Method to act during a time step
   * pick a random direction and move some random amount up to top speed
   */
  public void act()
  {
    // Decrease satisfied time, until hungry again
    satisfied--;

    // get the closest deer within some specified distance
    AgentNode closeDeer = getClosest(30,
                                     (AgentNode) mySim.getDeer().getNext());

    if (closeDeer != null)
    { // Even if deer close, only eat it if you're hungry.
      if (satisfied <= 0)
      {Deer thisDeer = (Deer) closeDeer.getAgent();
        this.moveTo(thisDeer.getXPos(),
                    thisDeer.getYPos());
        thisDeer.die();
        satisfied = MAX_SATISFIED;

      }
    }
 else
    {

      // if the randome number is > prob of turning then turn
      if (randNumGen.nextFloat() > PROB_OF_TURN)
      {
        this.turn(randNumGen.nextInt(360));
      }

      // go forward some random amount
      forward(randNumGen.nextInt(maxSpeed));

    }
  }
```

The difference between HungryWolf and Wolf instances is that hungry wolves will eat, but satisfied ones will not. So after the HungryWolf finds a close deer, it considers whether it's hungry. If so, it eats the deer. If not, that's the end of act() for the HungryWolf. The Hungry Wolf only wanders aimlessly if it finds no deer.

How do we make the simulation work with HungryWolf? We only have to change the code in the run() method so that hungry wolves are created instead of normal wolves. *Everything else just works!* Because a HungryWolf is a kind of Wolf, all references to wolves work for hungry wolves.

```
// create some wolves
   int numWolves = 5;
   for (int i = 0; i < numWolves; i++)
   {
     wolves.add(new AgentNode(new HungryWolf(w, this )));
   }
```

Writing results to a file

As we start making changes to our simulations, we would like to get a sense for what effects our changes are making. Certainly, we can see the number of wolves and deer left at the end of the simulation, but what if we care about more subtle changes than that. What if we want to know, for example, how *quickly* the deer die? Is it all at once, or over time? Is it all at first, or all at the end?

But even more important than being able to compare different runs of our simulation, we may care about the results of any given simulation. Maybe we are ecologists who are trying to understand a particular setting for wolves and deer. Maybe we are trying to make predictions about what will happen in a given situation. If your simulation is a video game, you just want to watch it go by. But if your simulation is answering a question for you, you probably want to get the answers to your questions.

There are three parts to creating a file of data that we can open up and analyze in Excel.

1. We need to open a *stream* to a file. A stream is a data structure that efficiently handles data that flows – goes in only one direction.

2. We need to be able to write strings to that stream.

3. We need to be able to handle exceptional events, like the disk becoming full or the filename being wrong.

Java handles all file input and output as a stream. It turns out that streams are useful for more than just files. For example, you can create large, sophisticated strings, say, of HTML, by assembling the string using output streams. An input stream might be coming from a file, but might also be coming from a network connection, for example.

It turns out that you've been using streams already. There is a stream associated with where you can print known as System.out. Thus, when you use the method System.out.println(), you are actually sending a string to System.out by printing it using println. There is also a stream that you might have used called System.err where errors are expected to be printed. And as you might expect, there is a stream called System.in for taking in input from the keyboard. All of this suggests one way of handling the second task: We can get strings to our stream simply by using println. We can also use a method named write().

To get a stream on a file, we use a technique called *chaining*. Basically, it's wrapping one object in another so that you get the kind of access you want. To get a stream for reading from a file, you'll need a BufferedReader to create a stream, and a FileReader for accessing the file. It would look something like **new** BufferedReader(**new** FileReader(fileName));.

Thus, there are three parts to writing to a file.

1. Open up the stream. writer = **new** BufferedWriter(**new** FileWriter(fileName));

2. We write to the stream. writer.write(data);

3. When done, we close the stream (and the file). writer.write(data);

Now, it's not enough to have a stream. Java requires you to deal with the *exceptions* that might arise when dealing with input and output (I/O). Exceptions are disruptions in the normal flow of a program. There is actually a Java class named Exception that is used in handling exceptions. Things can go wrong when dealing with output to a stream. What happens if the disk fills? What if the filename is bad? In other programming languages, there are ways for programmers to check if something bad has happened–and most programmers don't check. Java *requires* the programmer handle exceptions. The programmer can be specific (e.g., "If the disk fails, do this. If the filename is bad, do that.") or general (e.g., "If *anything* bad happens, here's how to bail out.").

There is a special Java statement just for handling exceptions. It's called **try**–**catch**. It looks something like this:

```
try {
\\code that can cause exceptions
} catch (ExceptionClassName varName) {
    \\code to handle this exception
} catch (ExceptionClassName varName) {
    \\code to handle that exception
}
```

You can deal with ("catch") several exceptions at once, of different types. If you do try to distinguish between exceptions in a single statement like that, put the most general one last, e.g., catch the general Exception, and maybe one like FileNotFoundException (for trying to open a file for reading

that doesn't exist) earlier in the list. All those other exceptions are subclasses of Exception, so catching Exception will handle all others. A general exception handling **try**–**catch** might look like this:

```
try {
\\code that can throw the exception
} catch (Exception e) {
    System.err.println( Exception:     + e.getMessage());
    System.err.println( Stack Trace is:   );
    e.printStackTrace();
}
```

That e in the above code is a variable that will be a reference to the exception object, if an exception occurs. Exceptions know how to do several different methods. One returns (as a String) the error message associated with the exception: e.getMessage(). Another prints out what all methods were currently running and at what lines when the exception occurred: e.printStackTrace().

There's an interesting variant on the **try**–**catch** that you should know about. You can specify a **finally** clause, that will always be executed *whether or not* exceptions occur.

```
try {
\\code that can cause the exception
} catch (FileNotFoundException ex) {
    \\code to handle when the file isn t found
} finally {
    \\code to always be executed
}
```

Putting it all together, here's how you would *read* from a file in Java.

```
BufferedReader reader = null;
String line = null;

// try to read the file
try {

  // create the buffered reader
  reader = new BufferedReader(new FileReader(fileName));

  // loop reading lines till the line is null (end of file)
  while ((line = reader.readLine()) != null)
  {
  // do something with the line
  }

  // close the buffered reader
  reader.close();

} catch (Exception ex) {
```

```
      // handle exception
    }
```

Now let's add a file output capability to our simulation. We want to be able to do this:

```
Welcome to DrJava.
> WolfDeerSimulation wds = new WolfDeerSimulation();
> wds.openFile("D:/cs1316/wds-run1.txt")
> wds.run();
```

The idea is that the simulation instance (named wds above) should be able to run with or without an open file. If there is a file open, then text lines should be written the text file–one per each time step. And after running the simulation timing loop, the file should be automatically closed.

The first step is to create a new instance variable for WolfDeerSimulation that knows a BufferedWriter instance. By default (in the constructor), the output file should be **null**.

```
/* A BufferedWriter for writing to */
 public BufferedWriter output;

 /**
  * Constructor to set output to null
  **/
 public WolfDeerSimulation() {
   output = null;
 }
```

We're going to use the idea of the output file being **null** to *mean something*. If the file is **null**, we'll presume that there is no file to be written to. While that may be obvious, it's important to consider with respect to those pesky exceptions discussed earlier in this section. What happens if we *try* to write to the file but something bad happens? If anything happens untoward to the file processing, we'll simply set output to file. Then, the rest of the code will simply presume that there is no file to write–even though there *was* one once.

For example, we'll give WDSimulation instances the knowledge of how to openFile()–but if anything bad happens, output goes back to **null**.

```
/**
  * Open the input file and
  * set the BufferedWriter to speak to it.
  **/
 public void openFile(String filename){
  // Try to open the file
   try {

     // create a writer
     output = new BufferedWriter(
               new FileWriter(filename));
```

```
    } catch (Exception ex) {
      System.out.println(
         "Trouble opening the file " + filename);
      // If any problem, make it null again
      output = null;
    }
  }
```

We need to change the bottom of the timing loop, too. We need to write to the file. But we *only* write to the file if output is not **null**. If an exception gets thrown, we set output back to **null**.

```
    // Let's write out where we stand...
    System.out.println(">>> Timestep: "+t);
    System.out.println("Wolves left: "+wolves.getNext().count());
    System.out.println("Deer left: "+deer.getNext().count());

    // If we have an open file, write the counts to it
    if (output != null) {
      // Try it
      try{
        output.write(wolves.getNext().count()+
            "\t"+deer.getNext().count());
        output.newLine();
      } catch (Exception ex) {
        System.out.println("Couldn't write the data!");
        System.out.println(ex.getMessage());
        // Make output null so that we don't keep trying
        output = null;
      }
    }
```

Check out the above for just a moment: Why are we saying wolves.getNext().count()? Why aren't we just saying wolves.count()? Remember that our count method counts every node from **this**. We haven't updated it yet for our head-rest list structure. Since the head of the list is empty, we don't want to include it in our count, so we start from its *next*.

After the timing loop, we need to close the file (if output is not **null**).

```
    // If we have an open file, close it and null the variable
    if (output != null){
      try{
        output.close();}
      catch (Exception ex)
      {System.out.println("Something went wrong closing the file");}
      finally {
        // No matter what, mark the file as not-there
        output = null;}
    }
```

Getting results from a simulation

We can use our newly developed ability to write out results of a simulation a text file in order to analyze the results of the simulation. From DrJava, using our new methods, we can write out a text file like this.

```
> WolfDeerSimulation wds = new WolfDeerSimulation();
> wds.openFile("D:/cs1316/wds-run1.txt")
> wds.run();
```

Our file is made up of lines with a number, a tab, and another number. Excel can interpret that as two columns in a spreadsheet.

Exercises

1. Change the Deer so that there is no random amount that it moves–it always zips around at maximum speed. Do you think that that would make more Deer survive, since they'll be moving so fast? Try it! Can you figure out why it works the way that it does? Here's a hint (that gives away what you can expect): Notice where the dead deer bodies pile up.

2. There is an inefficiency to this simulation, in that we return the closest AgentNode, but then we just pull the Wolf or Deer out of it. And then when a Deer dies, we get the Deer out of the AgentNode and call remove()–but the first thing that AgentNode's remove() does is to figure out the node containing the input Deer! These kinds of inefficiencies can arise when designing programs, but once you take a global perspective (considering what all the methods are and when they're getting called), we can improve the methods and make them less efficient. Try fixing both of these problems in this simulation.

3. Build the LinkedListNode class that can contain any kind of object. Make sure that AgentNode's remove works in that class.

4. The HungryWolf checks to see if there's a close deer *and then* decides whether or not it's hungry. Doesn't that seem silly? Change the HungryWolf act() method so that it checks if it's hungry *first*.

16 Abstracting Simulations: Creating a Simulation Package

Chapter Learning Objectives

It has finally become time to make those wildebeests and villagers. We're going to do it in two steps:

- First, we create a set of classes to make it easier to build simulations. We don't want to go to all the effort of the last chapter for every simulation we want to build. We'll build a few simulations using our new set of classes, to show both how easy it is to do and to show how we can use simulations to explore a model.

- Then, we'll map our turtles to characters in order to create simulations, like the wildebeests charging over the ridge in Disney's *The Lion King* or the villagers in the square in Disney's *The Hunchback of Notre Dame*.

The computer science goals for this chapter are:

- To create a set of classes that make it easier to make new applications, through subclassing.

- To create a variety of different kinds of simulations, more easily than creating simulations from scratch.

- To use pre-existing collection classes, rather than always building our own.

- To use the Java **switch** statement.

The media learning goals for this chapter are:

- To make animations from simulations by creating a mapping from turtle positions to animation images.

16.1 Creating a Generalized Simulation Package

While the Wolf and Deer Simulation is fun and interesting to explore, it was not easy to build. You might imagine that, if you wanted to build a variety of simulations to explore different models for a particular phenomenon, the effort to build simulations could dissuade you. You would be less likely to explore simulations if each one took the effort of the last chapter.

We can make it easier by providing a set of classes that define a basic, default simulation. We can construct these classes such that we *subclass* to create new, differentiated components. We *override* methods in order to define new, differentiated behavior.

Packages of functionality are often defined in object-oriented languages as a set of classes to be subclassed, extended, and differentiated. Object-oriented programmers spend much of their development effort finding appropriate classes and extending them in just this way—subclassing the provided class, and overriding methods to define the specific functionality that they need. In this chapter, we see both how a package of classes like that work, and how to extend a set of classes.

First, we have to tell the truth about data structures.

Real Programmers Rarely Build Data Structures

Thank you for willingly suspending your beliefs about data structures up until now. You may have been manipulating these linked lists and constructing these trees wondering, "I know lots of programmers, and they don't talk about doing things like this. Why am I doing this?"

The reality is that real programmers[1] rarely build data structures from basic objects and references as we have up until now. Very few programmers build arrays ever. Most programmers do not build lists, trees, hashtables, heaps, stacks, or queues.

These basic data structures are typically provided in the programming language. In the case of languages like Smalltalk and Python, some of these data structures, such as *hashtables*, are so important that they are a built-in feature of the language. A hashtable (also called a *dictionary* in Python, or an *associative array*) can be thought of like an array where the index can be something other than a number, often a string. Here's a short example from Python where person1 and person2 are each set up as dictionaries (by setting them to "{}"), and then are given values indexed by words like "name," "husband," and "wife."

```
>>> person1={}
>>> person1["name"]="Mark"
>>> person2={}
```

[1] Where "real programmers" can mean "professional programmers" or "people who program often" or even "people who already got through this class."

```
>>> person2["name"]="Barb"
>>> person1["wife"]=person2
>>> person2["husband"]=person1
>>> person1["name"]
'Mark'
>>> person1["wife"]["name"]
'Barb'
```

Hashtables are a key feature of Python and Smalltalk. The lists of methods that classes know, and the lists of variables that objects know are all implemented as a form of a hashtable. Python also builds in lists as a pre-defined structure. Smalltalk requires users to use a particular class (like OrderedCollection) for manipulating lists.

In other languages, such as Java, all the basic data structures are provided in a set of data structures called the *Collection Classes*. The various data structures (such as *HashMap* which is a Java hashtable, and *ArrayList* which is a kind of list) are defined in classes that you then instantiate like any other object in Java. These are particularly good implementations that are designed to be as fast as possible and use as little memory as possible.

```
> import java.util.*
> ArrayList v = new ArrayList()
> v.add(1)
true
> v.add(2)
true
> v
[1, 2]
> HashMap dict = new HashMap()
> dict.put("name","Mark")
null
> dict.get("name")
"Mark"
```

The bottom line is that few programmers, in any object-oriented language, ever write data structures on their own. There are several good reasons for this. First, it is difficult to implement these data structures to make them as fast and efficient as possible. It serves everyone well to use a single implementation that is very well constructed. Second, the critical issues with which most programmers deal are about applications and features that users need, not the low-level issues of how to make the hashtable look up keys particularly fast.

Now, there *are* times when programmers build data structures. Sometimes, a programmer may need a particular data structure that is not defined. Sometimes, a programmer may think of a data structure with particular features that would be appropriate for a given application. However, these times rarely happen.

Real Programmers Make Models and Choices

What real programmers[2] do *all* the time is define models. for example, what is the best way to represent the relationship between a hospital and its rooms? Maybe this hospital is really defined in terms of clinics, and the rooms are related to the clinics. How many of each are there? Are all rooms the same, or are their types (classes?) of rooms? How about clinics—all the same, or different types/classes? Figuring out how the real world is constructed, in terms that allow us to construct models that we can implement and manipulate on the computer, is what we do all the time.

Real programmers use the same modelling techniques that we saw in the last chapter. We use *aggregation* when we connect a hospital to its rooms or its clinics. We use *generalization-specialization* when we define types of rooms and clinics, then specialize them for particular kinds of rooms or clinics.

While real programmers do not implement data structures from scratch often, they are *always* making choices among data structures for the best ones to use in implementing their models. For this reason, it is important for a programmer to understand data structures, down to the level of how they are implemented in scratch, in order to make these choices.

- Some of these choices are made on the basis of functionality. The line of patients waiting for a particular test or treatment is probably best modeled as a queue. Are the rooms in the hospital best modeled as a long array or list of rooms? Or are they better clustered in terms of floors or clinics? That sounds more like a tree. Or maybe they are better listed by their room number that encodes floor, clinic, and room like "2A-350," and perhaps a hashtable is the best data structure to model the structure.

- Some of these choices are made on the basis of speed. Those decisions are typically made based on what we want to *do* with the model. We could use an array or list to track all of the patients in our hospital, perhaps sorted by last name or patient identification number. Imagine, though, that we need to match patients for possible blood or tissue transportation. Matching may take place based on factors such as blood type, tissue type, allergies or illnesses. Searching the array or list based on all those factors may take too long. If we clustered the patients using a tree, where branches represent different blood types, then tissue types, and then other factors, we could find similar patients quickly.

While you will rarely do *exactly* what we have been doing in these chapters, you will often make *decisions* based on this knowledge. That is why

[2]There is some difference in nomenclature here. Some might call the job we are describing here "systems analysis" or simply "being a computer scientist." Any of those are fine with us.

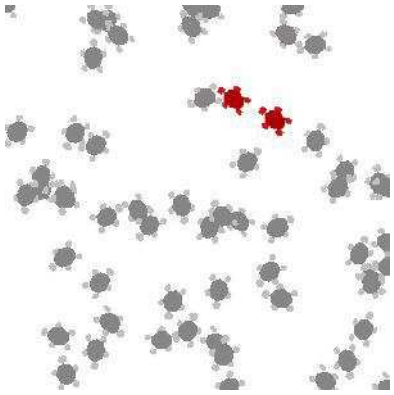

Figure 16.1: Sample of disease propagation simulation

we went through the process of constructing the data structures ourselves. From here on, we will be using the data structures provided by Java in order to create models for our simulations.

The Structure of the Simulation Package

To provide a goal for our simulation package, let's work on defining three different simulations:

- We should re-create our Wolves and Deer predator-prey simulation. If you are working from an existing implementation to a more generalized implementation, it's a useful exercise to make sure that you can still create the original application.

- We will build a simulation of *disease propagation* (Figure 16.1). In our simple form, one person is ill, and all the 60 people in the simulation walk around aimlessly. If the sick person gets close to a healthy person, the healthy person gets sick, too.

- We will build a simulation of *political influence* (Figure 16.2). Again, in a simple form, there are people with one kind of political conviction ("Reds") and others with another conviction ("Blues"). Each has a region of their own—to the left and to the right. Each moves around, and there is an overlap area. If a Red gets surrounded by more Blues than Reds, then the Red is argued down and converts to Blue. If a Blue gets surrounded by more Reds than Blues, then the Blue is converted to Red.

The general structure of the simulation package is described by the UML diagram in Figure 16.3.

Figure 16.2: A Political Influence Simulation

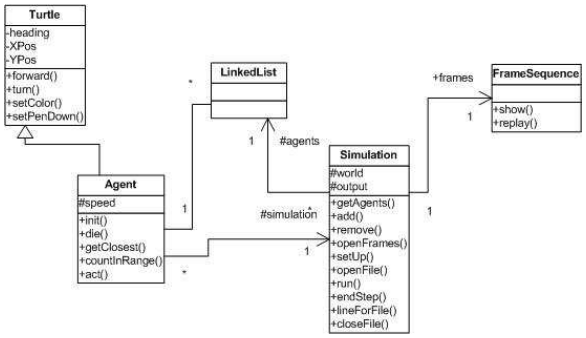

Figure 16.3: UML diagram of the base Simulation Package

- All of the actors in our simulations will be subclasses of the class Agent, which is a subclass of Turtle. Instances of Agent will then track their (x, y) position and heading within the world, as instances of Turtle do. In addition, Agent instances know which simulation that they are part of.

- Simulations are an instance of the class Simulation. Each simulation defines the general way that simulations work, e.g., how many actors and of what types enter the simulation, and when. An instance of Simulation also knows a FrameSequence in order to create an animation from the simulation sequence of Turtle/Agent motions.

- Each instance of Simulation maintains a list of all the Agent instances that are alive and active in the simulation. We will use an instance of the Java collection class LinkedList to track these agents.

To build a simulation using our simulation package, we will subclass Simulation to create our own simulation class, and we will subclass Agent for each class of actors in our simulation. We will override methods that are in the superclass in order to define the specifics of our simulation and

the behavior of our actors. We do not *have to* override the methods. The basic Simulation and Agent classes define perfectly reasonable simulations and actors. Whenever we want to use that pre-defined behavior in our overriding methods, we can call **super** (e.g., **super**.die()) to ask for the default behavior to occur.

The basic methods of Simulation are summarized in Table 16.1. When you create a new subclass of Simulation, you will almost always override setUp since you will want to put some agents in the simulation. The base setUp method simply opens up a World, with no actors in it. You will override other methods as you need.

Method	**Meaning**
getAgents(), add(), remove()	Returns or manipulates the list of valid agents.
setUp()	Define the simulation, e.g., the number of agents.
openFile()	Starts to write data to a file.
openFrames()	Starts to write frames of an animation.
run()	For a given number of timesteps, ask each living agent to act
endStep()	Processes the end of a time step.
lineForFile()	Returns a string to write to a data file. By default, write out the number of agents.
closeFile()	Close the data file for writing.

Table 16.1: Basic methods of Simulation class

The basic methods of Agent are listed in Table 16.2. The constructor for Agent takes the World instance in which the turtle should be created and the instance of the Simulation in which the actor lives. Often, a subclass of Agent will override init in order to do something special with the creation of the actor. Almost always, the subclass will override act in order to do something specific to the simulation.

Note that getClosest and countInRange expect a LinkedList of Agents to search. If an actor needs to search all the agents, then each instance can use the simulation field and ask for simulation.getAgents() to get the list of all agents. If, however, the simulation calls for checking just *some* agents, then a LinkedList of *just those* agents needs to be maintained. We'll see that in two of our three example simulations.

Using a LinkedList from the Java Collection Classes

The Java *API* (Application Programmer Interface) documentation describes what LinkedList instances know. Some of these methods are summarized in Table 16.3. You will notice that these methods look like they could be

Method	Meaning
init(Simulation sim)	Initialize a new agent, e.g., add it to the liv agents list.
act()	At each time step, each agent is asked to act(By default, wander aimlessly.
setSpeed(int speed), getSpeed()	Change the maximum speed of the agent in th World.
die()	Make the body red and remove from the agent list.
getClosest(LinkedList agents)	Return the agent from the list of agents closes to this agent.
countInRange(double range, LinkedList agents)	Count the number of agents within range of me

Table 16.2: Basic methods of Agent class

provided for just about any data structure, including arrays and ArrayList instances. In fact, these methods *do* work for just about every collection.

So why pick one collection versus another? You choose based on what you expect to be doing with the collection, and how fast you want the method to be. Will you be doing a lot of insertions into the middle of the list, like with add(**int** index, Object element)? If so, then a LinkedList would make an excellent choice. Will you be mostly getting a value from a given index, as with get(**int** index)? Then you know that an array would be much faster.

Do also notice that some of the methods that we have come to know and love in our linked list implementations, like insertAfter are *not* in Java's LinkedList class. The Java Collection Classes, to the extent possible, have exactly the same methods for each class. The reason is to enable the programmer to swap between different collection classes with minimal changes required to your code. Not sure whether to use a LinkedList or an ArrayList? Try each of them—your code using the collection (either one) will stay the same.

On the other hand, there are some things that you might want to do where you want to take advantage of the structure of the linked list. You might *want* to do insertAfter. In those cases, you may want to use your own linked list implementation. As a programmer, you have to consider the trade-off between using a pre-existing, well-debugged, and efficient collection class and thus saving yourself using the development time, versus the effort of developing your own version and being able to take advantage of the special functionality or speed optimizations that you can implement for yourself.

Method	Meaning
add(int index, Object element)	Adds the element into the list at position index—all other elements are pushed down to make room.
add(Object element)	Adds element to the end of the list
addAll(Collection c)	Adds each element from the input collection to the end of the list
addAll(int index, Collection c)	Adds each element from the collection, starting at the index
addFirst(Object element)	Adds the element at the start of the list
addLast(Object element)	Adds the element at the end of the list
clear()	Removes all elements from the list
clone()	Returns a copy of the list
contains(Object element)	Returns true if element is in the list
get(int index)	Returns the element at position index
getFirst(), getLast()	Returns the element at the front, or end (respectively), of the list
indexOf(Object element)	Returns the index value where the (first, if there are duplicates) element is in the list.
lastIndexOf(Object element)	Returns the last index where the element is found in the list
remove(int index)	Removes the element at index
removeFirst(), removeLast()	Removes the first or last element
set(int index, Object element)	Puts the element into position index, replacing if something else is there
size()	Returns the number of elements in the list

Table 16.3: Methods understood by instances of LinkedList

16.2 Re-Making the Wolves and Deer with our Simulation Package

A good test of our simulation package is making the wolves and deer simulation again, this time with the simulation package. If it is much easier this time, while still getting the same functionality as we had before, then that is a good indication that we are on the right path our package.

A UML diagram of the simulation package classes with the classes needed for the Wolves and Deer simulation appears in Figure 16.4. All that gets added here are the three classes at the bottom.

- WDSimulation is the subclass of Simulation that sets up the wolves and deer. Notice that it has no instance variables and only two methods. WDSimulation needs to setUp the wolves and deer, and it overrides

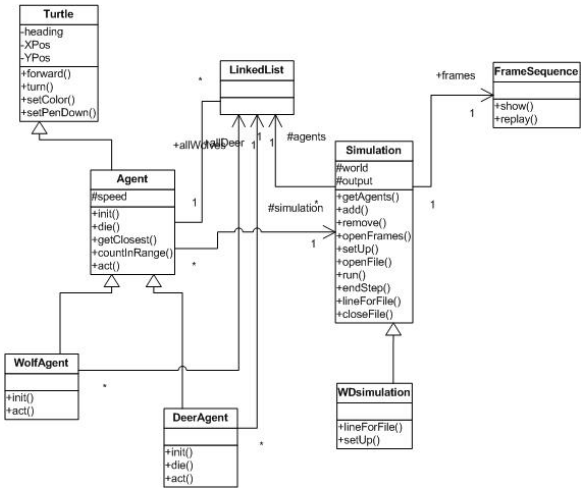

Figure 16.4: UML class diagram for Wolves and Deer with the Simulation Package

lineForFile in order to write out the number of wolves and deer separately.

- WolfAgent redefines init in order to set up wolf-specific behavior and fields (e.g., making them gray). One new static field is a LinkedList of allWolves. WolfAgent also overrides act in order to define the wolf-specific behavior of chasing and eating deer.

- DeerAgent redefines init and act in just the same ways, e.g., a static field named allDeer keeps track of deer agents. DeerAgent also overrides die, in order to remove the dead deer from the allDeer list, as well as the overall agents list.

Let's see how WDSimulation is defined. Remember that we only need two methods.

Program Example #113

Example Java Code: **WDSimulation's setUp() method**

```
/**
 * WDSimulation -- using the Simulation class
 **/
public class WDSimulation extends Simulation {

  /**
   * Fill the world with wolves and deer
```

```
   **/
  public void setUp(){
    // Let the world be set up
    super.setUp();

    // Just for storing the new deer and wolves
    DeerAgent deer;
    WolfAgent wolf;

    // create some deer
    int numDeer = 20;
    for (int i = 0; i < numDeer; i++)
    {
      deer = new DeerAgent(world,this);
    }

    // create some wolves
    int numWolves = 5;
    for (int i = 0; i < numWolves; i++)
    {
      wolf = new WolfAgent(world,this);
    }

  }
```

How it works: The setUp method first calls the superclass (**super**.setUp()) in order to create the World. Then 20 deer and 5 wolves are created in the world. Notice that the constructor for DeerAgent and WolfAgent echoes the constructor for Agent. Each Agent instance needs to know its World instance and its Simulation instance (**this** in this method).

Example Java Code: **WDSimulation's lineForFile() method** *Program Example #114*

```
 /**
   * lineForFile -- write out number of wolves and deer
   **/
  public String lineForFile(){
    // Get the size (an int), make it an Integer,
    // in order to turn it into a string. (Whew!)
    return (new Integer(DeerAgent.allDeer.size())).toString()+"/t"+
      (new Integer(WolfAgent.allWolves.size())).toString();
  }
```

* * *

How it works: WDSimulation wants to write out the number of deer and the number of wolves, separated by a tab, so that the numbers can be put in Excel and graphed. What we see here is that each of the classes DeerAgent and WolfAgent are asked for their list of live members, allDeer and allWolves respectively. The size() of these lists is converted to a string by making an Integer from the number (**new** Integer) and then converted using toString. A tab character is inserted using "/t," and the pieces are concatenated using "+."

Next, we'll tour each of WolfAgent and DeerAgent. From the UML class diagram, we are only expecting to see five methods.

Program Example #115

Example Java Code: **DeerAgent's init method**

```
import java.awt.Color; // Color for colorizing
import java.util.LinkedList;

/**
 * DeerAgent -- Deer as a subclass of Agent
 **/
public class DeerAgent extends Agent {

  /** class constant for the color */
  private static final Color brown = new Color(116,64,35);

  /** class constant for how far deer can smell */
  private static final double SMELL_RANGE = 50;

  /** Collection of all Deer */
  public static LinkedList allDeer = new LinkedList();

 /**
   * Initialize, by adding to Deer list
   **/
  public void init(Simulation thisSim){
    // Do the normal initializations
    super.init(thisSim);

    // Make it brown
    setColor(brown);

    // Add to list of Deer
    allDeer.add(this);
  }
```

* * *

How it works: We see many of the same variables that we saw in our previous Deer class. A new static field is allDeer. We need this field to be **static** because we want *one* list that is shared by all the deer. We do *not* want each deer to have a normal instance variable allDeer—we do not want to maintain the list (e.g., adding new deer, removing old deer) in each and every DeerAgent instance. The method init does the normal initialization of agents (**super**.init(thisSim)) which adds the agent to the list of all agents. Then deer are made brown and members of the allDeer list.

Example Java Code: **DeerAgent's die() method** *Program Example #116*

```
/**
  * To die, do normal stuff, but
  * also remove from deer list
  **/
 public void die(){
   super.die();
   allDeer.remove(this);
   System.out.println("Deer left: "+allDeer.size());
 }
```

How it works: When deer die, they do the normal things (e.g., turn red, and be removed from the agents list so that they stop moving) via **super**.die(). Then, they get removed from the allDeer list. For interest's sake, we're printing out the number of deer still alive whenever one dies.

Common Bug: Removing from only one list

What would happen if you forgot the **super**.die() in the above code? Then the deer would still be removed from the allDeer list, but still be in the simulation agents list. The deer would still be told to act, so the deer would run around and flee from wolves. But since the deer wouldn't be on the allDeer list, the deer would never be found or eaten by wolves, since that's the list that wolves look at.

What would happen if you forgot the allDeer.remove(**this**) instead? Now, the deer are not on the agents list, so they never are told to act and they never move. However, wolves can still find them and eat them.

This is the trouble of maintaining multiple lists—you have to add and remove from them in synchrony.

* * *

Program Example #117

Example Java Code: **DeerAgent's act() method**

```
/**
 * How a DeerAgent acts
 **/
public void act()
{
  // get the closest wolf within the smell range
  WolfAgent closeWolf = (WolfAgent) getClosest(SMELL_RANGE,
                                    WolfAgent.allWolves);

  if (closeWolf != null) {
    // Turn to face the wolf
    this.turnToFace(closeWolf);
    // Now directly in the opposite direction
    this.turn(180);
    // How far to run? How about half of current speed??
    this.forward((int) (speed/2));
  }
  else {
    // Run the normal act() -- wander aimlessly
    super.act();
  }
}
```

How it works: We know how deer are supposed to act, so we can compare the above to our expectations. When a DeerAgent is told to act, it checks to see if it can smell a wolf, by looking for the closest agent from WolfAgent.allWolves (casted to a WolfAgent) within the SMELL_RANGE. If there is one, the deer faces the closest wolf, turns around, and runs away. If there isn't one, we simply do the default **super**.act() which involves wandering aimlessly.

Program Example #118

Example Java Code: **DeerAgent's constructors**

```
//////////////////////////// Constructors ////////////////////////
  // Copy this section AS-IS into subclasses, but rename Agent to
  // Your class.

  /**
   * Constructor that takes the model display (the original
   * position will be randomly assigned)
```

```
   * @param modelDisplayer thing that displays the model
   * @param thisSim my simulation
   */
  public DeerAgent (ModelDisplay modelDisplayer, Simulation thisSim)
  {
    super(randNumGen.nextInt(modelDisplayer.getWidth()),
          randNumGen.nextInt(modelDisplayer.getHeight()),
          modelDisplayer, thisSim);
  }

  /** Constructor that takes the x and y and a model
   * display to draw it on
   * @param x the starting x position
   * @param y the starting y position
   * @param modelDisplayer the thing that displays the model
   * @param thisSim my simulation
   */
  public DeerAgent (int x, int y, ModelDisplay modelDisplayer,
                    Simulation thisSim)
  {
    // let the parent constructor handle it
    super(x,y,modelDisplayer,thisSim);
  }
```

How it works: These constructors must be there because Agent has them, because Turtle needs a form of them. ModelDisplay is an **interface** that World implements. The first constructor, then, we recognize as the one we normally call when creating an Agent. The first form computes a random horizontal and vertical location, based on the width and height of the World, then calls the second one which places the agent at that (x, y) in the World for the thisSim instance of Simulation.

In general, constructors of this form need to be in every subclass of Agent. There is not much, if anything, to change with these. We will not show these in other agents—you will need to have them, still, Just copy-paste and change the name of the class.

Example Java Code: **WolfAgent's init method**

Program Example #119

```
import java.awt.Color;
import java.util.LinkedList;

/**
 * WolfAgent -- Wolf as a subclass of Agent
 **/
```

```
public class WolfAgent extends Agent {
  /** class constant for how far wolf can smell */
  private static final double SMELL_RANGE = 50;

    /** class constant for how close before wolf can attack */
  private static final double ATTACK_RANGE = 30;

  /** Collection of all Wolves */
  public static LinkedList allWolves = new LinkedList();

 /**
   * Initialize, by adding to Wolf list
   **/
  public void init(Simulation thisSim){
    // Do the normal initializations
    super.init(thisSim);

    // Make it brown
    setColor(Color.gray);

    // Add to list of Wolves
    allWolves.add(this);
  }
```

How it works: There really is not anything new here. Like the class Wolf, our WolfAgent has an ATTACK_RANGE. The rest of the code is identical to our DeerAgent—except, of course, that wolves are Color.gray rather than brown.

Program Example #120

Example Java Code: **WolfAgent's act() method**

```
 /**
   * Chase and eat the deer
   **/
    /**
   * Method to act during a time step
   * pick a random direction and move some random amount up to top speed
   */
  public void act()
  {
    // get the closest deer within smelling range
    DeerAgent closeDeer = (DeerAgent) getClosest(SMELL_RANGE,
                                    DeerAgent.allDeer);
    if (closeDeer != null)
    {
```

```
      // Turn torward deer
      this.turnToFace(closeDeer);
      // How much to move?  How about minimum of maxSpeed
      // or distance to deer?
      this.forward((int) Math.min(speed,
                    closeDeer.getDistance(this.getXPos(),this.getYPos())));
    }

    // get the closest deer within the attack distance
    closeDeer = (DeerAgent) getClosest(ATTACK_RANGE,
                            DeerAgent.allDeer);

    if (closeDeer != null)
    {
      this.moveTo(closeDeer.getXPos(),
                  closeDeer.getYPos());
      closeDeer.die();
    }

    else // Otherwise, wander aimlessly
    {

      super.act();
    } // end else
  } // end act()
```

How it works: Instances of the class WolfAgent act like the ones in Wolf. First, the wolf smells if there is a deer nearby:

```
DeerAgent closeDeer = (DeerAgent) getClosest(SMELL_RANGE,
                                  DeerAgent.allDeer);
```

If there is, the wolf turns toward the deer, and moves the *minimum* (Math.min) of the wolf's maximum speed and the distance to the deer. Why the minimum? It may be obvious to you now, but it was not to us when we first built this class. We had the wolf move full-speed toward the closest smelled deer—and we noticed that few deer were getting eaten. Then we noticed that the wolves would run toward the deer *and run past them!* That was when we realized that we need the minimum of the full-speed leap and the distance to the deer.

If there is no deer within the smell range, the wolf looks for a deer to attack. If there is one, the wolf moves there and the deer dies. Otherwise, the wolf wanders aimlessly via **super**.act().

We could run this simulation with a main method in WDSimulation, or we might just do it from the INTERACTION PANE:

```
Welcome to DrJava.
> WDSimulation wd = new WDSimulation();
```

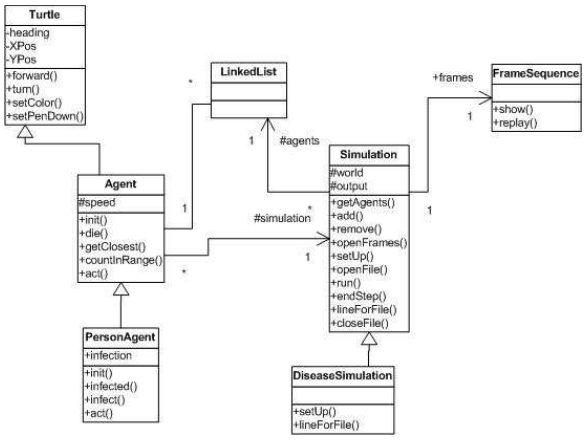

Figure 16.5: UML Class Diagram of Disease Propagation Simulation

```
> wd.openFrames("C:/temp/"); // If you want an animation
> wd.openFile("C:/cs1316/wds-data1.txt"); // If you want an output file.
> wd.run();  // By default, run for 50 steps
```

If you simply want to run the simulation, without frames or data written out, use:

```
WDSimulation wd = new WDSimulation();
wd.run(); // By default, run for 50 steps
```

16.3 Making a Disease Propagation Simulation

Next, let us see how hard it is to implement a new simulation using our package. Figure 16.5 describes the UML class diagram for the disease propagation simulation. Notice that we need to create only two new classes to implement the disease propagation simulation: DiseaseSimulation and PersonAgent.

- DiseaseSimulation overrides the same two methods as WDSimulation. It overrides setUp in order to create the simulation structure—here, a bunch of people where one of them is sick. It overrides lineForFile to separately list healthy and sick people. You will see that we get these counts *without* separate lists for this simulation.

- PersonAgent overrides init and act, just like the wolf and deer agents. PersonAgent has two other methods, that deal with infecting a person and counting the infected persons. The instances of PersonAgent have one additional field, a **boolean** (a variable that is only **true** or **false**) indicating whether the person has the infection.

* * *

am
ple #121

Example Java Code: **DiseaseSimulation's setUp method**

```
/**
 * DiseaseSimulation -- using the Simulation class
 **/
public class DiseaseSimulation extends Simulation {
/**
   * Fill the world with 60 persons, one sick
   **/
  public void setUp(){
    // Let the world be set up
    super.setUp();
    // Or set it up with a smaller world
    //world = new World(300,300);
    //world.setAutoRepaint(false);

    PersonAgent moi;

    // 60 people
    for (int num = 0; num < 60; num++) {
      moi = new PersonAgent(world,this);
    }

    // Infect the first one
    moi = (PersonAgent) getAgents().get(0);
    moi.infect();
  }
```

How it works: Basically, the setUp method makes 60 instances of PersonAgent. It picks the first one (which could be anywhere in the World, since agents are placed at random positions) via getAgents().get(0) and infects it. Notice that we first set up the world with **super**.setUp(), but we also have code there to create the World ourselves, but smaller than the default $(640, 480)$ world. We will play around with that later.

Program Example #122

Example Java Code: **WDSimulation's lineForFile method**

```
 /**
   * lineForFile -- write out number of infected
   **/
  public String lineForFile(){
    PersonAgent first;
```

```
    first = (PersonAgent) agents.get(0);
    return (new Integer(first.infected())).toString();
  }
```

How it works: Unlike the wolf and deer simulation, our PersonAgent class *computes* the number of different kinds of agents. In contrast, the wolf and deer simulations keep *track* of the wolves versus deer agents in two separate lists. It's an instance method that adds up the number of infected people, infected, so we can just grab any agent and ask it for the number of infected, then write it to a file.

Program Example #123

Example Java Code: **PersonAgent's init method**

```
import java.awt.Color; // Color for colorizing
import java.util.LinkedList;

/**
 * PersonAgent -- Person as a subclass of Agent
 **/
public class PersonAgent extends Agent {

  public boolean infection;
 /**
   * Initialize, by setting color and making move fast
   **/
  public void init(Simulation thisSim){
    // Do the normal initializations
    super.init(thisSim);

    // Make it lightGray
    setColor(Color.lightGray);

    // Don't need to see the trail
    setPenDown(false);

    // Start out uninfected
    infection = false;

    // Make the speed large
    speed = 100;
  }
```

* * *

How it works: PersonAgent defines the infection variable as a **boolean**—it is either **true** or **false**. By default, people are Color.gray and uninfected, with a fairly fast speed. They also do not have their pens set down—while that is the default condition for Agents, putting it in explicitly makes it explicit that we can turn it on, too. Sometimes, it's useful to see where the infected people wander and who comes in touch with them.

Example Java Code: **PersonAgent's act method**

Program Example #124

```
/**
 * How a Person acts
 **/
public void act()
{
  // Is there a person within infection range of me?
  PersonAgent closePerson = (PersonAgent) getClosest(10,
                                simulation.getAgents());

  if (closePerson != null) {
    // If this person is infected, and I'm not infected
    if (closePerson.infection && !this.infection) {
      // I become infected
      this.infect();
  }
  }

  // Run the normal act() -- wander aimlessly
  super.act();
}
```

How it works: PersonAgent's act method is the heart of the disease propagation simulation. This method is what each person does, once per time step. In this method, the infection range is 10. If there is a person within 10 steps (closePerson= null!), and this close person *is* infected (codePerson.infection) and I am *not* infected (this.infection!), then I become infected (**this**.infect()).

Example Java Code: **PersonAgent's infect method**

Program Example #125

```
/**
 * Become infected
 **/
public void infect(){
```

```
    this.infection = true;
    this.setColor(Color.red);

    // Print out count of number infected
    System.out.println("Number infected: "+infected());
  }
```

How it works: This is the method called when a person becomes infected. The **boolean** field infection is set to **true**—the person now has an infection. The person's color becomes Color.red. Purely for the fun of tracking, we print out the number infected.

Program Example #126

Example Java Code: **PersonAgent's infected method**

```
/**
  * Count infected
  **/
 public int infected() {
   int count = 0;
   LinkedList agents = simulation.getAgents();
   PersonAgent check;

   for (int i = 0; i<agents.size(); i++){
     check = (PersonAgent) agents.get(i);
     if (check.infection) {count++;}
   }

   return count;
 }
```

How it works: This is a straightforward count (called "*enumeration*") of elements meeting a particular criteria. We start with our count variable at zero. We get the list of all agents, and then using a **for** loop to increment an index variable i, we increment the count if the infection is **true** for the agent at index i. At the end, we return the count of infected persons.

A Problem and Its Solution: Enumerating elements of a particular type

We have now seen two ways of counting a particular kind of agent. With the wolves and deer, we kept two separate lists, and when needed, took the size of the lists. With persons who are infected or not, we instead have a *flag* (the **boolean** variable) in each person indicating infection, and keep

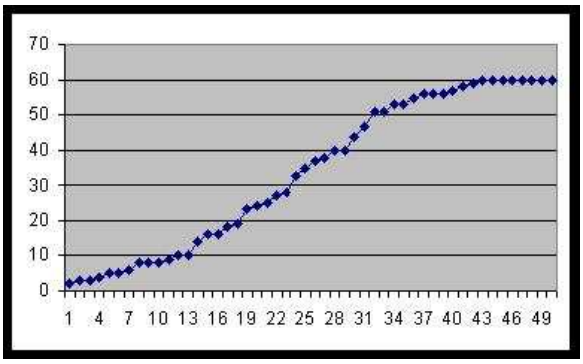

Figure 16.6: A graph of infection in the large world

just a single list of all the persons. When we need to count (enumerate) the sick persons, we go through the list of all persons and count up those for whom the flag is true. Which is better? It depends on what you need to do. If you just want to count, then keeping the single list is easiest. Maintaining separate lists is more complex, as we saw in how we added to the lists and removed (in the case of deer dying). In the wolves and deer case, we needed separate lists of each (for looking for near members), so it was worthwhile to go to the extra effort.

Now, we can run our disease propagation simulation, with code like this:

```
DiseaseSimulation ds2 = new DiseaseSimulation();
ds2.openFile(``C:/cs1316/disease-fullsize.txt'');
ds2.run();
```

Exploring Scenarios in Disease Propagation

There are lots of interesting scenarios to explore in disease propagation simulations. One of them is already set up in the code. When we run our simulation using some code like the above, we get a file with the number of infected people written out, one number per line, one line for each time step. That is perfect for reading into Microsoft Excel, Open Office Spreadsheet, or just about any other graphing tool.

First, we should look at what a typical run of our simulation looks like. Figure 16.6 shows a graph of one run of the simulation, set up exactly as described in this chapter. We see a steady increase in the number of infected people until we reach about timestep 43, at which point everyone is infected.

* * *

A Problem and Its Solution: How do we determine *typical* behavior?
No two runs of any of our simulations should ever be identical, not if Java's random number generator is working well. Since the decision for each agent to turn (or not) and how much to travel is driven by the random number generator, and the initial positions are all chosen randomly, and all other decisions in our simulations are based on agent locations, then our simulation results should be quite different for each run. How do we know, then, if a given result (e.g., of so many people infected in such an amount of time) is *typical*? If we ran the last scenario again, could it be that not everyone gets infected, or that everyone gets infected much sooner. This is exactly where *statistics* enter the picture. The goal of a hypothesis test (like a *t-test* or *chi-square test* is exactly to enter the question, "Did our study get a reasonable number of subjects? What are the odds that we happen to pick n oddball samples to study, and these are not at all typical?" We are not going to answer that question here. Instead, we point you to your next classes and to the connections between computer science, simulations, and probability and statistics.

Now, in DiseaseSimulation method setUp(), let us change how the world is setup. Change the commenting at the start so that it looks like this:

```
// Let the world be set up
//super.setUp();
// Or set it up with a smaller world
world = new World(300,300);
world.setAutoRepaint(false);
```

The two uncommented lines do the same thing as **super**.setUp(), but with a much smaller world—$300x300$ instead of $640x480$. Does that matter? Figure 16.7 is a graph of a run with the smaller world. It looks like it matters very much. In the smaller world, everyone is infected by timestep 25. Perhaps this is why diseases tend to spread much more quickly in tight-knit groups or in urban settings. If there are as many people, but everyone travels in a smaller area, people are more likely to bump into one another.

When we explore this simulation in class, we often run experiments like this exploration of greater or smaller space in the simulation. Sometimes we vary the number of people in the space, sometimes we have agents avoid visibly infected agents, and other times we change aspects of the disease. One semester, a student suggested a change to the disease where it kills infected people after three days, but their bodies would still lie around infecting others. (We might note that this was a particularly morbid student.) What was the impact on the infection rate? Surprising to all of us in the class, the infection rate *dropped* dramatically. When we mentioned this result to mathematical biologists, they were not at all surprised. That finding has been well-known by mathematical biologists. That is why the

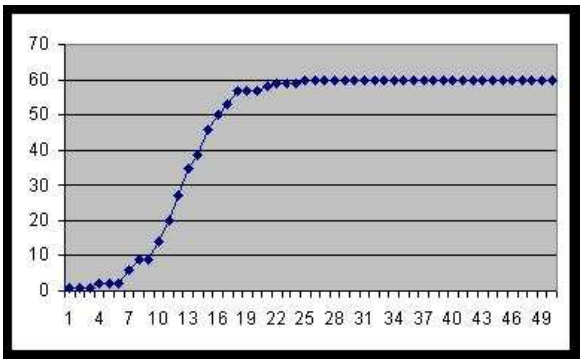

Figure 16.7: A graph smaller world disease propagation simulation

Ebola virus has not reached the general populace, we were told. When a disease agent kills rapidly, it also eliminates the opportunity for the infected people to spread the disease further.

16.4 Making a Political Influence Simulation

Simulations can also be used to explore social science questions. In this simulation, we explore ways in which political influence might spread among members of different political affiliations. Figure 16.8 presents a UML class diagram for the political simulation that we will be developing in this chapter. The simulation only requires two new classes.

- PoliticalSimulation has a setUp for the simulation (creating Red and Blue agents, and moving them to their home sides), and special methods for lineForFile and endStep.
- PoliticalAgent has a new instance field called politics that describes the agent's current affiliation. It overrides init and act, and provides a new method for setPolitics.

Remember that there are two sets of PoliticalAgents, Red and Blue. Both wander aimlessly, but within constraints. Blue is only to the right, and Red is only to the left. There is an overlap in their areas of influence for 200 pixels in the middle. If a Blue gets surrounded (argued down?) by more Red supporters than Blue supporters, the Blue turns Red, and the reverse is also true.

Example Java Code: **PoliticalSimulation's setUp method** *Program Example #127*

```
import java.awt.Color;
/**
```

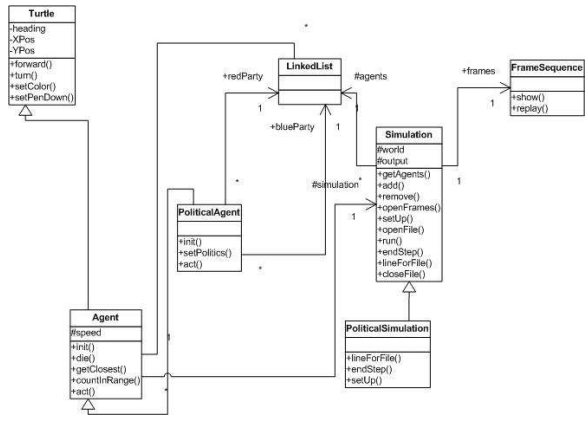

Figure 16.8: UML class diagram of political simulation

```
 * PoliticalSimulation -- using the Simulation class
 **/
public class PoliticalSimulation extends Simulation {

/**
   * Fill the world with 60 persons
   **/
  public void setUp(){
    // Let the world be set up
    super.setUp();

    PoliticalAgent moi;

    // 60 people
    for (int num = 0; num < 60; num++) {
      moi = new PoliticalAgent(world,this);
      // First 30 are red
      if (num < 30) {
        moi.politics = Color.red;
        moi.moveTo(100,100);
        PoliticalAgent.redParty.add(moi);
      }
      else {
        moi.politics = Color.blue;
        moi.moveTo(500,100);
        PoliticalAgent.blueParty.add(moi);
      }
      moi.setColor(moi.politics);

    } // for loop
```

```
} // setUp()
```

How it works: The basic PoliticalSimulation has 60 people, the first 30 of whom are Color.red and the next 30 are Color.blue. The politics variable for each *is* a color. Each is created at the home base for the party. Notice that each are added to a LinkedList that is **static** (accessed through PoliticalAgent) for the redParty or the blueParty.

Because the world is 640 across, not 600, the Blue party has more space. Is that an advantage? Does that improve their odds of having more Blue members?

Example Java Code: **PoliticalSimulation's lineForFile and endStep methods** *Program Example #128*

```
/**
 * lineForFile -- write out number of each party
 **/
public String lineForFile(){

  return (new Integer(PoliticalAgent.redParty.size())).toString()+"\t"+
    (new Integer(PoliticalAgent.blueParty.size())).toString();
}

/**
 * EndStep, count the number of each
 **/
public void endStep(int t){
  super.endStep(t);

  System.out.println("Red: "+PoliticalAgent.redParty.size()+" Blue: "+
                     PoliticalAgent.blueParty.size());
}
```

How it works: Each of these is about tracking the number of number of members of each party. lineForFile writes out each of the sizes of the LinkedList's holding those party members. EndStep displays on the console the number of each, at the end of each timestep.

Example Java Code: **PoliticalAgent's init method** *Program Example #129*

```
import java.awt.Color; // Color for colorizing
import java.util.LinkedList;

/**
 * PoliticalAgent -- Red or Blue Stater as a subclass of Agent
 **/
public class PoliticalAgent extends Agent {

  // Red or Blue
  public Color politics;

  public static LinkedList redParty = new LinkedList();
  public static LinkedList blueParty = new LinkedList();

  /**
   * Initialize
   **/
  public void init(Simulation thisSim){
    // Do the normal initializations
    super.init(thisSim);

    // Don't need to see the trail
    setPenDown(false);

    // Speed is 100
    speed = 100;

  }
```

How it works: Notice that the politics field is actually of type Color. The class PoliticalAgent also defines the two LinkedList **static** fields that list the members of each party. We are using the separate list method because we are going to want to count the number of one party surrounding the other. The rest of the init method is completely ordinary.

Program Example #130

Example Java Code: **PoliticalAgent's setPolitics method**

```
 /**
   * Set politics
   **/
  public void setPolitics(Color pref){
    System.out.println("I am "+politics+" converting to "+pref);

    if (pref == Color.red) {
      blueParty.remove(this);
```

```
      redParty.add(this);
      this.politics = pref;}
    else {
      blueParty.add(this);
      redParty.remove(this);
      this.politics = pref;
    }
    this.setColor(pref);

  }
```

How it works: The setPolitics method does three things, after figuring out which party an agent *currently* belongs to. It removes the agent from the party list of the *old* party, adds the agent to the *new* party's list, then sets the politics field. At the end, the color of the agent is to the politics color.

Example Java Code: **PoliticalAgent's act method**

Program Example #131

```
/**
  * How a PoliticalAgent acts
  **/
 public void act()
 {
   // What are the number of blues and red near me?
   int numBlue = countInRange(30,blueParty);
   int numRed = countInRange(30,redParty);

   if (politics==Color.red){
     // If I'm red, and there are more blue than red near me, convert
     if (numBlue > numRed){
       setPolitics(Color.blue);}
   }
   if (politics==Color.blue){
     // If I'm blue, and there are more red than blue near me, convert
     if (numRed > numBlue) {
     setPolitics(Color.red);}
   }

   // Run the normal act() -- wander aimlessly
   super.act();

   // But don't let them wander too far!
   // Let them mix only in the middle
   if (politics==Color.red) {
```

```
      if (this.getXPos() > 400) { // Did I go too far right?
        this.moveTo(200,this.getYPos());}
    }
     if (politics==Color.blue) {
      if (this.getXPos() < 200) { // Did I go too far left?
        this.moveTo(400,this.getYPos());}
     }

  }
```

How it works: The PoliticalAgent act method is one of the more complicated we have seen. (If you want to *change* any of the political influence rules of this simulation, here is where to do it!) The first step is to count the number of Red and Blue party members near this agent. Then, there is a series of nested **if** statements to figure out which political party **this** agent is affiliated with, and if the numbers require a change.

After considering the change, *all* agents wander aimlessly (**super**.act()). Then, we consider whether the political agent has wandered into the enemy's camp. If so, the agent is moved to the edge of the overlap zone that is closest to that party's home base. (Would it change anything if the agent was moved to the far edge, rather than the edge of the boundary zone?)

Obviously, this is a highly simplified model of political influence. One might increasingly add more conditions. Perhaps Red members are more stubborn and it takes more Blue members to convert a Red than Red members to convert a blue. Perhaps a newly converted Blue is immune to conversion for a couple of weeks (14 timesteps?). Some agents are probably more persuasive and charismatic than others—they might have different influences. These are some of the scenarios that might be explored in a simulation like this.

16.5 Walking through the Simulation Package

We are not going to walk through *all* of the simulation package in this chapter. For the most part, it looks like the Wolves and Deer Simulation of the last chapter. What is useful to understand is how the *overriding* works. When do methods get called in Simulation, Agent, a particularly Simulation subclass, and a particular Agent subclass?

Let's *trace* the execution of the disease propagation simulatoin from:

```
DiseaseSimulation ds = new DiseaseSimulation();
ds.run();
```

The first line executes the *constructor* for the class. Since DiseaseSimulation does not have its own constructor, we will call the one in **Simulation**:

```
public Simulation() {
    // By default, don't write to a file.
    output = null;
```

```
    // And there is no FrameSequence
    frames = null;
  }
```

The method run is in the **Simulation** package. Note that there is a run() that accepts no inputs, and a run(**int** timeRange) that defines the number of steps to execute. Executing ds.run() calls the first method:

```
/**
  * Run for a default of 50 steps
  **/
 public void run(){
   this.run(50);
   this.closeFile();
 }
```

And it in turn executes the second version. Here are the first few lines of that method.

```
/**
  * Ask all agents to run for the number of input
  * steps
  **/
 public void run(int timeRange)
 {
   // A frame, if we're making an animation
   Picture frame;

   // For storing the current agent
   Agent current = null;

   // Set up the simulation
   this.setUp();
```

When we get to this step in Simulation's run method, we ask **this** (which is our DiseaseSimulation instance in variable ds) to setUp(). **DiseaseSimulation** does have a setUp() method, so we will call that.

```
/**
  * Fill the world with 60 persons, one sick
  **/
 public void setUp(){
   // Let the world be set up
   super.setUp();

   PersonAgent moi;

   // 60 people
   for (int num = 0; num < 60; num++) {
     moi = new PersonAgent(world,this);
   }
```

```
    // Infect the first one
    moi = (PersonAgent) getAgents().get(0);
    moi.infect();
  }
```

The *very first* line in this method, though, calls **super**.setUp() which executes **Simulation**'s setUp() method.

```
public void setUp(){
    // Set up the World
    world = new World();
    world.setAutoRepaint(false);
  }
```

After executing this method, we return to the rest of DiseaseSimulation's setUp() method, which creates the 60 people, one ill. We are now back in **Simulation**'s run(**int** timeRange) method. We just finished the setUp() method, so we go on to the time loop:

```
    // Set up the simulation
    this.setUp();

    // loop for a set number of timesteps
    for (int t = 0; t < timeRange; t++)
    {
      // loop through all the agents, and have them
      // act()
      for (int index=0; index < agents.size(); index++) {
        current = (Agent) agents.get(index);
        current.act();
      }
```

Each of current in this loop is a PersonAgent. Does **PersonAgent** have an act() method? Sure does!

```
public void act()
 {
    // Is there a person within infection range of me?
    PersonAgent closePerson = (PersonAgent) getClosest(20,
                                simulation.getAgents());

    if (closePerson != null) {
      // If this person is infected, and I'm not infected
      if (closePerson.infection && !this.infection) {
        // I become infected
        this.infect();
    }
    }

    // Run the normal act() -- wander aimlessly
    super.act();
  }
```

Note that at the end of this method, we call **super**.act(). This means that **Agent**'s act() method will then execute. This is the method that implements wandering aimlessly.

```
public void act()
 {
   // Default action: wander aimlessly
   // if the random number is > prob of NOT turning then turn
   if (randNumGen.nextFloat() > PROB_OF_STAY)
   {
     this.turn(randNumGen.nextInt(360));
   }
   // go forward some random amount
   forward(randNumGen.nextInt(speed));
 } // end act()
```

We then return to **Simulation**'s run(**int** timeRange) method. After each agent is asked to act(), the world gets updated (world.repaint()). If there is a simulation, a frame gets written out.

```
      // repaint the world to show the movement
      world.repaint();
      if (frames != null){
        // Make a frame from the world, then
        // add the frame to the sequence
        frame = new Picture(world.getWidth(),world.getHeight());
        world.drawOn(frame);
        frames.addFrame(frame);
      }

      // Do the end of step processing
      this.endStep(t);

      // Wait for one second
      //Thread.sleep(1000);
    }
```

We then execute the endStep method. Since DiseaseSimulation does not have one, we call **Simulation**'s endStep method.

```
public void endStep(int t){
   // Let's figure out where we stand...
   System.out.println(">>> Timestep: "+t);

   // If we have an open file, write the counts to it
   if (output != null) {
     // Try it
     try{
       output.write(this.lineForFile());  // NOTE THIS LINE!
       output.newLine();
     } catch (Exception ex) {
       System.out.println("Couldn't write the data!");
```

```
            System.out.println(ex.getMessage());
            // Make output null so that we don't keep trying
            output = null;
            }
        }
    }  // endStep()
```

But wait! In the middle of that method is a call to **this**.lineForFile(). **DiseaseSimulation** *does* have a lineForFile() method!

```
public String lineForFile(){
    PersonAgent first;
    first = (PersonAgent) agents.get(0);
    return (new Integer(first.infected())).toString();
}
```

That ends the execution for *one* call to an act() method for *one* agent in *one* timestep. This process of calling between the different classes and methods happen for *every* agent for *every* timestep. Fortunately, processors are really fast.

You do not really have to know what is inside of Simulation nor Agent to use the package. The important thing to know is what methods to override, and how (and when) your methods will be called. This walkthrough should give you a better sense of how the code in your subclasses gets called, and when the methods in the superclass gets used.

16.6 Finally! Making Wildebeests and Villagers

After hundreds of pages, we can *finally* create an animation that is generated from a simulation! This is a similar method to what is used in Disney's *The Lion King* when the wildebeest's charged over the ridge or in *The Hunchback of Notre Dame* when the villagers milled about in the square.

The basic process is quite simple. We write a simulation, using the same approach seen previously in the chapter. Each agent should represent one character in our simulation. At each timestep, we create a *new* frame and draw our character images in the frame. We will use exactly this approach in creating our movie about the birdlike beings investigating the mysterious egg (Figure 16.9).

Here is the story of this movie. The turtle-like curious bird-things[3] wander, slowly, toward the mysterious egg. As they get up close to it-it opens its eyes and shows its fangs! They scamper away while the monster shifts around and looks to the left and right.

Your first reaction is likely, "How is this unlike the wolvies attacking the village movie?" Yes, it is quite similar. However, in this version, the

[3]We made these quickly, unsure whether we wanted turtles or birds. Since then, we have left them in their quasimodo state because they serve as a low bar for future movie makers. Certainly, *anyone* can make better looking characters than these!

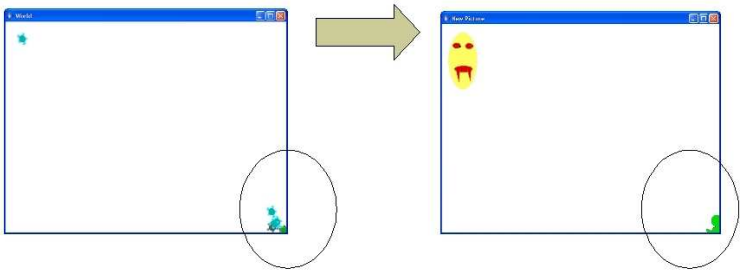

Figure 16.9: Mapping from agent (turtle) positions on the left to character positions on the right

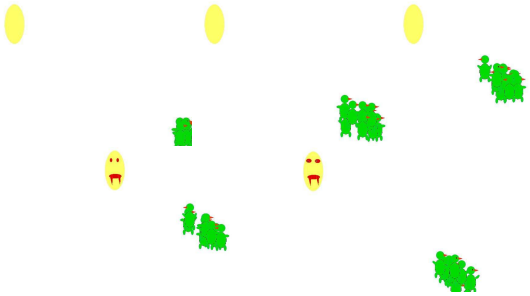

Figure 16.10: Frames from the Egg-Bird Movie

positions of the investigating birds are not scripted. They emerge from the random number generator. We could easily run the simulation again to get a different movie—we can have as many "takes" as we may like.

There are three classes in this simulation:

- BirdSimulation sets up the birds and the egg. The real work of the *mapping* occurs in the method endStep().
- BirdAgent defines the behavior of the birds.
- EggAgent defines the behavior of the egg.

We are going to make a couple of changes to Agent and Simulation as we go along, in order to make the mapping work more easily to the animation. These changes do not interfere with the previous simulations in this chapter. In fact, the Java class files that you have been using (assuming you have been experimenting all along here) already have all of these changes. One change creates a character image for mapping to the agent, and another change allows us to get a time step number in act() in case we want to do something in a particular frame.

* * *

Program Example #132

Example Java Code: **BirdSimulation's setUp method**

```
/**
 * BirdSimulation
 * A flock of 10 birds investigate a mysterious egg,
 * which suddenly shows itself to be a monster!
 **/
public class BirdSimulation extends Simulation {

  public EggAgent egg; // We'll need to get this later in BirdAgent
  FrameSequence myFrames; // Need a separate one from Simulations

  /**
   * Set up the world with 10 birds and the mysterious egg
   **/
  public void setUp(){
    // Set up the world
    super.setUp();
    // We'll need frames for the animation
    myFrames = new FrameSequence("/home/guzdial/temp/");
    myFrames.show();

    BirdAgent tweetie;
    // 10 of 'em
    for (int num = 0; num < 10; num++) {
      tweetie = new BirdAgent(world,this);}

    // And the egg
    egg = new EggAgent(world,this);
  }
```

How it works: After seeing three simulations previous to this one, it's pretty clear what's going on here. We create 10 birds and one egg. One difference is the creation of a FrameSequence for storing our simulation frames.

Program Example #133

Example Java Code: **BirdSimulation's endStep method**

```
 public void endStep(int t) {
    // Do the normal file processing (if any)
    super.endStep(t);
```

```
    // But now, make a 640x480 frame, and copy
    // in pictures from all the agents
    Picture frame = new Picture(640,480);
    Agent drawMe = null;
    for (int index=0; index<this.getAgents().size(); index++) {
      drawMe = (Agent) this.getAgents().get(index);
      drawMe.myPict.bluescreen(frame,drawMe.getXPos(),
                               drawMe.getYPos());
    }
    myFrames.addFrame(frame);
  }
```

How it works: This method does the mapping process. At the end of each time step, we create a picture to store our frame. For each agent, we get its picture (drawMe.myPict) and then use bluescreen to draw the picture at the position drawMe.getXPos(), drawMe.getYPos() of the turtle/agent. We then add the frame to the frame FrameSequence.

We modified Agent to have this new field:

```
public class Agent extends Turtle
{

  /////////////// fields ////////////////////
  // NEW - for copying onto frame
  public Picture myPict;
```

The other change we need is to get the frame number passed into act, if the agent wants it. This is a fairly tricky change. We want the Agent subclasses to get the frame number (time step number—same thing) if it wants it, but we do not want to require an input to act(). Here's how we solve it: We change the run method in Simulation to pass a time step number, but we also provide an implementation in Agent that accepts a time step number and calls act() without an input. In this way, if the time step is not needed, the other version of act() gets called.

Program Example #134

Example Java Code: **Changing Simuation's run() method for a time step input to act()**

```
// loop through all the agents, and have them
      // act()
      for (int index=0; index < agents.size(); index++) {
        current = (Agent) agents.get(index);
        current.act(t); // NEW -- pass in timestep
      }
```

* * *

Program Example #135

Example Java Code: **Changing Agent to make time step inputs optional**

```
/**
   * act() with a timestep
   **/
  public void act(int t){
    // By default, don't act on it
    this.act();
  }
```

Now we can build our agents.

Program Example #136

Example Java Code: **BirdAgent's init method**

```
/**
 * BirdAgents use the bird character JPEGs
 **/
public class BirdAgent extends Agent{

  public static Picture bird1, bird2, bird3, bird4, bird5, bird6;

  /**
   * Set up the birds
   **/
  public void init(Simulation thisSim){
    if (bird1 == null) {
      // Do we have the bird characters defined yet?
         bird1 = new Picture(FileChooser.getMediaPath("bird1.jpg"));
      bird2 = new Picture(FileChooser.getMediaPath("bird2.jpg"));
      bird3 = new Picture(FileChooser.getMediaPath("bird3.jpg"));
      bird4 = new Picture(FileChooser.getMediaPath("bird4.jpg"));
      bird5 = new Picture(FileChooser.getMediaPath("bird5.jpg"));
      bird6 = new Picture(FileChooser.getMediaPath("bird6.jpg"));
   }

   // Start out with myPict as bird1
    myPict = bird1;

    // Do the normal initializations
```

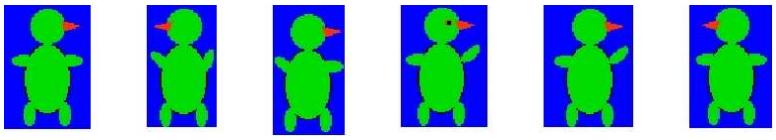

Figure 16.11: The individual images for the bird characters

```
    super.init(thisSim);

    // Move all the birds to the far right corner
    this.setPenDown(false);
    this.moveTo(600,400);

    // Set speed to relatively slow
    this.setSpeed(40);

  }
```

How it works: Since all our bird characters will look the same (Figure 16.11)[4], we simply load them all into a set of **static** variables. No, they do not *have* to be static, but we also do not need to waste the space since they will all look the same. We use a trick here to load the six images. When the first bird is created, bird1 will be **null**. We then load all six images. The rest of the birds will check if bird1 is **null**, but of course, it won't be. All birds will start out with the first image, and down in the lower right hand corner of the world.

Example Java Code: **BirdAgent's act method** *Program Example #137*

```
/**
  * act(t) For first 20 steps, walk toward the egg,
  * +/- 30 degrees.
  * Then walk AWAY from the egg, and with MORE wandering (panic).
  **/
 public void act(int t){
   // First, handle motion
   if (t <= 20) {
     // Tell it that this really is a BirdSimulation
     BirdSimulation mySim = (BirdSimulation) simulation;
     // which has an egg
     this.turnToFace(mySim.egg);
```

[4] See previous explanation for the birds' look-and-feel

```
      this.turn(randNumGen.nextInt(60)-30);
      forward(randNumGen.nextInt(speed));
    } else {
      // Run away!!
      this.turnToFace(640,480); // Far right corner
      this.turn(randNumGen.nextInt(80)-40);
      forward(randNumGen.nextInt(speed));
    }
   // Next, set a new character
    int cell = randNumGen.nextInt(6)+1; // 0 to 5, + 1 => 1 to 6
    switch (cell) {
      case 1:
        myPict = bird1;
        break;
      case 2:
        myPict = bird2;
        break;
      case 3:
        myPict = bird3;
        break;
      case 4:
        myPict = bird4;
        break;
      case 5:
        myPict = bird5;
        break;
      case 6:
        myPict = bird6;
        break;
    } // end switch
  } // end act
```

How it works: This is an act method that takes a time step as an input, t. The birds act different in the first 20 frames, and the rest of the movie. During the first 20 frames, the birds always head toward the egg (which we will see is in the upper left-hand corner). They turn a bit while heading there. The formula randNumGen.nextInt(60)−30 means that a random number between 0 and 59 will be generated, then 30 will be subtracted from that. The result is a value between −30 and 29. The birds will generally be meandering toward the egg. The birds then move forward at a random value based on their speed.

Once the egg becomes scary in frame 20, the birds face the opposite corner. The range of variance is larger for turning, from −40 to 39—they are more choatic running away.

No matter what the frame is, the birds consider changing their look with every frame. A die is thrown, using randNumGen.nextInt(6)+1 to store

a value between 1 and 6 in the variable cell. A **switch** statement is used to make a choice.

Think of a **switch** statement as a shortcut for a bunch of **if** statements. Read:

```
switch (cell) {
  case 1:
    myPict = bird1;
    break;
  case 2:
    myPict = bird2;
    break;
```

as:

```
    if (cell == 1)
            {myPict = bird1;}
    else if (cell == 2)
            {myPict = bird2;}
```

The **break** says "Only one **case** is going to match, so skip to the end of the **switch** statement now."

Example Java Code: **EggAgent's init method** *Program Example #138*

```
/**
 * EggAgent -- big scary egg that sits there until t=15,
 * then emerges as a monster!
 **/
public class EggAgent extends Agent {

  public static Picture egg1, egg2, egg3, egg4;

  /**
   * To initialize, set it up as the Egg in the upper lefthand corner
   **/
  public void init(Simulation thisSim){
    if (egg1 == null) { //Initialize
        egg1 = new Picture(FileChooser.getMediaPath("egg1.jpg"));
      egg2 = new Picture(FileChooser.getMediaPath("egg2.jpg"));
      egg3 = new Picture(FileChooser.getMediaPath("egg3.jpg"));
      egg4 = new Picture(FileChooser.getMediaPath("egg4.jpg"));
    }
    // Start out as egg1
    myPict = egg1;

    // Normal initialization
    super.init(thisSim);
```

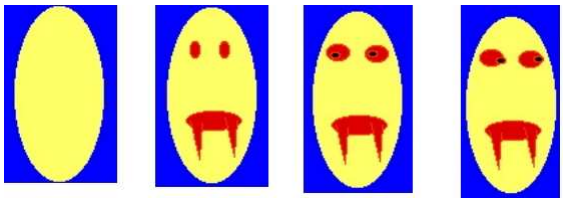

Figure 16.12: The various egg images

```
    // Move the egg up to the left hand corner
    this.moveTo(10,10);
  }
```

How it works: The EggAgent init method works much as the BirdAgent's does. First, the four egg images are loaded into static methods. The egg starts looking like the first one—just a plain ordinary egg (Figure 16.12). The egg (remember that only one instance of EggAgent is created) is in the upper left hand corner.

Program Example #139

Example Java Code: **EggAgent's act method**

```
/**
  * To act, just drop the Egg for 15 steps,
  * then be the eyes opened for five steps,
  * then be the eyes switching back-and-forth
  **/
 public void act(int t) {
   if (t < 19) {
     myPict = egg1;}

   if (t>19 && t<24) {
     myPict = egg2;}

 if (t>23) {
     int choose=randNumGen.nextInt(2);
     if (choose == 1) {
       myPict = egg3;}
    else {
      myPict = egg4;}
   }
 } // end act()
```

* * *

How it works: The EggAgent is the only agent we have seen that never moves at all—not aimlessly, not towards an object. For the first 19 frames, the egg just sits there. Then, the eyes open at frame 20—that's the egg2 image in Figure 16.12. After frame 23, the egg randomly shifts between the final two images, where the eyes shift left-and-right.

Going Beyond the Wildebeests

And that's it! We've now figured out the basic computer science behind the wildebeests and the villagers!

There are lots of interesting things to do with even this simple bird animation.

- Birds could start out all over the screen, and slowly move themselves toward the egg—then all run away in the same direction. That might have more visual impact.
- Rather than use frame numbers in the BirdAgent act(), the egg could have a method like looksScary(). Then, instead of checking for the frame number, the BirdAgent could ask **if** (egg.looksScary()) in order to decide to run away. The code would be less complex and read more easily.
- The birds could respond to one another, like avoiding crowds.

Perhaps the biggest idea here is that mapping a simulation to an animation is just *one* kind of mapping that one could create. An animation is only one kind of representation to make from a simulation. How about playing certain sounds or MIDI phrases from different characters when they act at different times? Music could be a result of a simulation as well as an animation is.

Despite the interestingness of continuous simulations, they are not the most common kinds of simulations. The most common kinds of simulations, and perhaps the most useful for answering people's questions, are *discrete event simulation*. So even though we have finished our journey to the wildebeest's here, we are going to have one more chapter to finish our exploration of the usefulness of simulations.

16.7 A Tour of Java Collection Classes

An overview of Java's Collection Classes will appear in this space...

Exercises

1. Do the first exercise from the last chapter, with this new WDSimulation: "Change the Deer so that there is no random amount that it moves–it

always zips around at maximum speed." How much harder or easier is it?

2. PersonAgent's act method is not quite right. Rather than asking if there's an infected person within range of me, it asks who the closest person is to me and if that person is infected. Fix the act method so that it does the right thing.

3. Using the Simulation Package developed in this chapter, create a simulation of an ecology. Use classes WolfAgent, DeerAgent, and a new CornAgent (that you will write), and your simulation should extend the Simulation class.

   Setup your simulation like this:

   - Create a dozen deer and three wolves to start.
   - Create three dozen pieces of corn.

   When running your simulation, let's consider a timestep to be about a week. Run the simulation for 2 years (104 timesteps). Here are the basic rules for the simulation.

   - Deer can smell wolves within 20 steps and will move away from them. (Initial max speed is 20.)
   - Wolves can smell deer within 15 steps and will move to them, kill the deer, and eat it. (Initial max speed is 25.)
   - Deer can smell corn within five steps and can move to it within a single step. If a deer lands on a corn, it eats the corn.
   - If a deer goes two weeks without corn, it's speed drops by half. Once it eats corn, its speed goes back to maximum.
   - If a deer goes four weeks without corn, it dies.
   - If wolves go five weeks without a deer, their speed drops by half. Once a wolf eats a deer, its speed goes back to maximum
   - If a wolf goes ten weeks without a deer, it dies.
   - If corn survives for twelve weeks, it grows two more corn plants next to itself (any direction). *Every* twelve weeks, it can have two more children.
   - Store to a file the number of wolves, deer, and corn each time step.

   An important part of this exercise is to do *experimentation*. Run this simulation with these rules, three times. Then try two other sets of rules and run each of those three times, also. Your goal is to reach equilibrium that there are roughly as many Deer, Corn, and Wolves as you start out with at the end of the Simulation.

   Things that you might want to try changing in your rules:

- *Initial counts.* Should there be more Corn, or fewer Deer? Would culling the herd help more survive? Would more Wolves create better equilibrium?
- *Ranges.* Should Deer or Wolves smell only closer, or farther? Should they not be able to jump to Corn or Deer in a single time step?

For extra credit, implement male and female Deer. Every twelve weeks, the female Deer can become pregnant if there is a male Deer within smell range. (You decide if the female jumps to the male, or the male jumps to the female.) Pregnancy lasts for six weeks, during which time the female will die if she doesn't get corn every *three* timesteps. At the end of six weeks, a new Deer is produced (randomly selected gender).

In addition to your program, you are to produce a report with graphs of all *nine* of your runs that's three runs of each of three sets of variables. Show all three variables Wolves, Deer, and Corn per timestep for all three of the scenarios that you explored. Explain what you changed in each scenario and why you think the results differed from the other scenarios.

4. Using the Simulation Package developed in this chapter, create a simulation of immigration behavior.

   Here's the initial setup:

   - Create a World that is 400 x 400. (If your world gets crowded, you're welcome to make it bigger.)
   - The rightmost 200 pixels represent Europe. The leftmost 100 pixels represent America.
   - Create 150 People scattered across Europe.

   When running the simulation, let's consider a timestep to be about a month. Run the simulation for 10 years (120 timesteps). Here are the starting (overly simplistic and not historically accurate) rules.

   - If a person has over five neighbors within 20 pixels for three consecutive timesteps, then that person feels overcrowded and decides to emigrate to America.
   - There is a 10% probability for each person in Europe that they experience crop failure each timestep. If a person experiences crop failure, they decide to emigrate to America.
   - There is only 5% chance that someone moves somewhere else in Europe in a timestep, and if they do, they only move between 1 and 16 steps away. (And always within Europe not into the Atlantic.)

- It takes three timesteps to cross the Atlantic. 10% of those that start the journey don't make it across. (That's not 10% per timestep it's 10% of the number of people.) Be sure to show the people making the journey, about 33 steps per timestep. (Note that it is easier to compute a $1/10$ chance of dying each emigration timestep. That is a reasonable simplification, but it's not really the same thing.)
- Once a person moves to America, they move more often (20% chance of moving each timestep, in a range of 1 to 100 pixels, but always within America), but disease is common there. 2% of the population in America becomes diseased (maybe changes color?) each timestep (they don't move when sick). 50% of those ill get healthy again each timestep. If someone is ill for four timesteps in success, they die.
- Store to a file the number of people in Europe, in transit, and in America each time step.

Again, *experiment*—use these initial rules to start, and try two other scenarios. Here are some issues that you might want to try changing in your rules:

- *Overcrowding.* Maybe there are more people to start with, or it takes more too-close neighbors to convince someone that they're overcrowded, or more timesteps of crowded conditions to convince them to move
- *Crop failures.* What if crop failures were more common, or it took multiple consecutive crop failures to convince someone to emigrate.
- Travel. What if people didn't die on the trip over, or if it took longer.
- Movement. What if people moved more often, or further, in either America or Europe.
- Disease. In America, more crowded conditions would lead to higher probabilities of disease. What if people moved like they do in Europe, or if they all came ashore at the same two or three spots (e.g. *Ellis Island*), and then the incidence of disease was dependent on the number of people around you.
- Wealth. Add the additional variables of wealth and cost to the simulation and come up with reasonable rules for how this wealth is used in the simulation. Europeans may have a normal distribution of wealth, but perhaps with a wide variance. The least wealthy are more likely to get sick, more likely to have crop failure, and are more likely to want to emigrate. The most wealthy are the least likely to want to emigrate, are less likely to have

crop failure, and are less likely to get sick. Once in America, wealth still plays a factor (most of the *Founding Fathers* were quite wealthy)—an interesting question is what kind of distribution of wealth appears in America given the rules that you set out and which Europeans emigrate. Wealth plays less of a role in movement, but still plays a role in whether you get sick and die.

Produce a report with graphs of all *nine* of your runs that's three runs of each of three sets of variables. Show all three variables—Europeans, in-transit, and Americans per timestep for all three of the scenarios that you explored. Explain what you changed in each scenario and why you think the results differed from the other scenarios.

Note: It is particularly fun to generate this simulation as a series of JPEG frames, then create a movie from them!

5. Using the simulation package developed in this chapter, and replacing the turtle with character images, create a crowd scene simulation. Start out with 100 villagers scattered around the world.

   During the simulation, let's imagine that a time step is a minute. Run the simulation for 90 minutes.

   - If there is no one around a villager (say, within 50 steps), the villager will set a heading for the closest person and take a couple of steps that way.
   - If there are three or more people too close (say within 10 steps), a villager will get out of there (pick a random direction and move speed distance away not a random speed, but actual speed.) (It's pretty hard to set a heading toward open space, but if you can do it, go ahead!)
   - In general, people are milling about. They take 1–5 steps per time step. They have only a 10% chance of changing direction of movement. They change physical position regularly—25% chance each time step of changing the direction they're facing, 5% chance each time step of waving (i.e., putting hand up, putting it down next time step). Implement any other milling–about rules (e.g., more position changes) you'd like.
   - 10 minutes into the simulation, the Nasty Bad Dude (or *Dudess*, as you wish), walks into the World. The NBD doesn't change direction, and just walks 2–5 steps per time step. But the villagers don't want to be anywhere near the NBD! If the NBD is near (say, within 30), they walk exactly away (turn towards, then turn 180, and move). Nobody ever sets a heading *toward* the NBD anymore. They quietly just start milling away from the NBD as s/he walks across the world.

This simulation aches for generating JPEG movies in order to see the resultant movie! (You may notice some similarities between this situation and the crowd scenes in Disney's *The Hunchback of Notre Dame*.)

6. Using the simulation package developed in class, and replacing the turtle with character images, create a stampeding crowd scene simulation.

   At the beginning of the simulation, have 100 crowd members (wildebeests?) on the left edge of the world (within 100 pixels of the left edge). All headings are initially set to the right edge. Have ten "obstacle" agents scattered in the middle 200 pixels of the world

   During the simulation, let's imagine that a time step is a minute. Run the simulation for 30 minutes.

   - The crowd moves relentlessly from the left edge to the right, with a minimum movement each step being 3 pixels, and a maximum of 10 steps.
   - The crowd doesn't want to be bumping into others. If there are three or more people too close (say within 10 steps), a person will get out of there (pick a random direction and move speed distance away not a random speed, but maximum speed.) (It's pretty hard to set a heading toward open space, but if you can do it, go ahead!)
   - Nobody in the crowd wants to be within 10 steps of an obstacle. If someone is heading for an obstacle, and they're within 20 steps of the obstacle, they're going to turn 45 degrees to the left or right (randomly). (What if they're NOW heading for an obstacle, after turning? Better turn again! Find some direction where you're NOT facing an obstacle!)
   - People change physical position regularly—25% chance each time step of changing the direction they're facing, 5% chance each time step of doing something else(waving? i.e., putting hand up, putting it down next time step). Implement any other milling about rules (e.g., more position changes) you'd like.
   - If at the start of a timestep, you're not facing the right edge, start heading back that way. Change your heading by 10 degrees each time step to head toward the right edge (e.g., if your heading is 5, and you want to be 90, change to 15).

   This might sound like the charging of the wildebeests in Disney's *The Lion King*.

7. Using the simulation package developed in this chapter, and replacing the turtle with character images, create a simulation of the *Running of the Bulls in Pamplona*.

Setup the simulation with a world that is 800 pixels long, but only 75 wide. Create 25 runners at $x = 50$ in the world. Create 5 bulls at the leftedge, $x = 0$

During the Simulation, let's imagine that a time step is a minute, and run the simulation for 30 minutes. You decide on the parameters like max speed and ranges to create a good looking simulation.

- The runners move from the left edge to the right, but they do wander from side-to-side some always within the lane.
- Bulls also move relentlessly from the left edge to the right, but if a bull gets close to a runner, it moves toward that runner.
- The runners don't want to be bumping into others. If there are three or more people too close (say within 10 steps), a person will get out of there (pick a random direction and move speed distance away not a random speed, but maximum speed.)
- If a runner gets close to a bull, the runner will double their max speed for one time step just to get ahead of the bull.
- If a bull catches a runner, the runner is then injured (maybe dead?) and stops. All of the bulls and the rest of the runners keep going.
- Runners change physical position regularly sometimes they're watching over their left, sometimes over their right, and sometimes they're running straight ahead. You must have at least three different positions for runners that your animations move through.
- If at the start of a timestep, you're not facing the right edge, start heading back that way. Change your heading by 10 degrees each time step to head toward the right edge (e.g., if your heading is 5, and you want to be 90, change to 15).

8. Enhance the disease propagation simulation into something much more fiendish now.

   - People, once infected (come within 10 steps of an infected person), don't turn red for two days though they do spread the disease. There is a 0.05 possibility that an infected person NEVER becomes red but does spread the disease. Call those the "*Typhoid Mary*" carriers.
   - Healthy people, if they get within 20 steps of a *visibly* infected person (someone red), turn away. But, of course, some people are not visibly carrying the disease, but are infected.
   - After 5 days of becoming infected, 25% of the people die. Their bodies remain infected and spreading the disease, but they are

red so that people can tell to avoid them. The rest of the infected people become non-red at day 6 and become un-infected at day 7. (Yes, there is one day at the end when they are not visibly infected, but they are still infected.)

Implement these rules and note the average number of people infected (normal size world, start with 100 people and one infected) and the average number dead over three runs. Run your simulation for 100 time steps.

The goal is to *increase* the number that survive and decrease the number of people who become infected. Implement *two* of the below public health policies. Implement one of the policies, try out three runs and compute the average infected and dead, then implement the second policy and compute the average infected and dead. Produce a report with graphs of the number of healthy, infected, and dead people for each of the 100 days of each run. Your report should have 3 graphs for the original rules, then 3 graphs after the first policy implementation and a description of what happened (including average counts of diseased and dead) and why, then 3 graphs after both policies are implemented with a description of what happened with counts and why.

POLICIES:

- Reduce mobility of the sick: When someone becomes visibly infected (red), their speed drops in half.
- Reduce mobility of the healthy: Decrease from the start the speed of all people (so they don't bump into the infected as much).
- Voluntary quarantine of the sick: When someone is visibly infected, at the beginning of each step, they turn to face $(640, 480)$. That way, sick people will tend to move toward the lower right.
- Voluntary segregation of the sick and healthy. Visibly infected people turn to face $(640, 480)$, and healthy (or presumably healthy those that are non-red) people turn to face $(0, 0)$.
- Mandatory quarantine of the sick: At the beginning of the step for visibly infected, they *immediately move* to $(640, 480)$. They can move some from there, but they always go back to their quarantine spot.
- Mandatory quarantine of the sick and healthy: All visibly infected move to $(640, 480)$, and all visibly healthy people move to $(0, 0)$.
- Removal of the Dead (the *Monty Python's Holy Grail*'s "bring out your dead!" policy): All dead bodies immediately go to $(640, 0)$. (Presume that people in bioprotection suits are moving the dead without becoming infected themselves.)

- Scarce Vaccine (the Chosen Few policy): Five people (probably national leaders or doctors or police) are given vaccines when first created. They never become infected.
- The Paranoid Policy: Everyone stays away from everyone else.

9. Use the Simulation Package and your any disease simulation (including the enhanced one from the previous exercise), and create an animation from it.

   Implement:

   - Three different types of people they can be different genders, different looks, etc.
   - A difference between healthy people and sick people (but not all people show the sickness, if you are using an enhanced disease) That means that that each of the three different types of people must have a different look in sickness and health.
   - There must be 3 different positions of each type of people facing left, facing right, moving left, moving right. You must rotate among these positions, perhaps with a probability of 0.3 of changing position with each time step.
   - Dead people should look different from healthy or sick people

   That is a total 3 positions x 3 types x 2 (sick or healthy) = 18 images that you need to have for the living people, plus one more image for dead people.

10. (*Advanced*.) All of our simulations are flawed in that activity (death, political change, infection) occurs *within* the timestep. That means that the *order* in which agents are processed will change the simulation, e.g., if a person goes from Red to Blue, then that changes the number of Blue for his or her neighbor, or a wolf may move toward a deer that gets eaten in the same time step by another wolf. A better way to do this is to consider all changes *before* making *any* changes. This is called a *transaction model*—all transactions occur at once. Change the Simulation and Agent classes so that all our simulations work, but are based on a single transaction.

17 Discrete Event Simulation

> Anyone who considers arithmetical methods of producing random digits is, of course, in a state of sin. — John von Neumann (1903-1957)

Chapter Learning Objectives

The difference between continuous and *discrete event simulations* is that the latter only represent *some* moments of time—the ones where something important happens. Discrete event simulations are powerful for describing (and allowing us to make predictions about) a wide variety of situations including supermarkets, factory floors, hospitals, and economies. In order to create this simulations, we will use *random distributions* to describe behaviors when we do not know all the relevant factors. There are many kinds of random distributions, not just the simple random number generator that we have used so far. Once we make things happen randomly, we have to make sure that we keep *time order* true—first things come first, and next things come next. We will use a couple of different ways of maintaining reality order, by sorting events into the right order, and by inserting events into reality order.

The computer science goals for this chapter are:

- To use queues to maintain order in a simulation.
- To use normal and uniform random distributions.
- To use both sorting and insertion into sorted order to maintain a monotonically increasing notion of time.

The media learning goals for this chapter are:

- To explore the use of simulations to generate animations, music, and more.

17.1 Describing a Marketplace

Imagine this scenario:

- You are in charge of a small business that you would like to optimize.

- You have three trucks that bring product from the factor to the warehouse. On average, they take three days to arrive, but it could take two days (if traffic and police are light) or four or more (if weather acts up or there is engine trouble). Each truck brings somewhere between 10 and 20 units (all values between there equally likely, depending on production issues).
- You have five distributors who pick up product from the warehouse with orders. Usually they have orders ranging from 5 to 25 units, all equally likely.
- It takes the distributors an average of two days to get back to the market, and an average of five days to meet with customers, deliver the products, and take new orders.

There are lots of items you might wonder about this situation.

- How much product gets delivered like this?
- Do distributors have to wait for product? How long do they have to wait? How long does the line get?
- How much product sits in the warehouse?
- What would help us move more product? Having more trucks or larger trucks? Moving the warehouse closer to the factory? Moving the warehouse closer to the market? Having more distributors?

You do *not* want a continuous simulation to explore this situation. You do not care about every moment. There will be days in this simulation where nothing happens at all. You want specific answers to specific questions—you want to know the exact times that events occur. The animation of distributors and trucks moving between the factory, warehouse, and market is not important to answering these questions. You don't care, for example, how close trucks and distributors are to one another.

What you *do* need is an *discrete event simulation*. You want to represent the *specific* events that you are interested in. You want to skip all the rest of them. You want to control the random distributions and the interactions between components of the simulation.

17.2 Differences between Continuous and Discrete Event Simulations

Discrete event simulations are quite different from continuous simulations. Now you understand continuous simulations well, we can describe these differences in terms of how we construct the simulation.

There is no time loop in discrete event simulations. In continuous simulations, we wanted to represent all time values from 1 to the number of

time steps that we want to simulate. In a discrete event simulation, we run until we *pass* a given time. Time values do not come from a loop. Instead, events (like a distributor arriving at the warehouse, or a truck arriving at the factory) lead to computation of when the *next* event will occur. We run the simulation from one event time to the next event time. If nothing ever happens on day two of the simulation, that means that no event occurs on day two, and we simply skip it. It never occurs in our simulation.

The key here is that we must keep a list of events to occur *in the order that they should occur*. Imagine that a distributor arrives at the marketplace, and schedules an event to occur to leave the marketplace five days later. A second later, a truck leaves the factory, and it schedules the event to arrive at the warehouse two days later. In reality, the truck would arrive at the warehouse before the distributor leaves the marketplace. We generated the events in the reverse order, however. We have to be sure to make sure that we *simulate* the events in the correct, realistic order.

Time travel is really easy in a discrete event simulation, and the same dangers of creating contradictions exist. Imagine that the distributor arrives at the warehouse, and there's no product, so the distributor starts waiting for a truck. The truck then arrives—three days earlier. Did the distributor just wait for a negative three days?

Agents do not *act()* in a discrete event simulation. If there is no timing loop, there is no loop in which we say to each agent, "It's your turn to do something!" The notion of only executing *events* means that the whole idea of giving every agent a "turn" is wrong.

Agents only do something when their event occurs. When an event occurs, the agent gets the chance to handle the event. Unless the agent dies in the event, the agent should then schedule the *next* event to occur. The agents do that using the random distributions relevant to their activities.

Introducing Resources

A big difference between continuous and discrete event simulations is the use of *resources*. Agents in a discrete event simulation cannot do everything they want all the time. What is interesting about the scenarios in which you use discrete event simulations is the interaction between agents and in the struggle for resources.

Resources in our scenario are *products*. Trucks deliver them, and distributors distribute them. Distributors cannot do their job until the trucks do their jobs, so that the products arrive. The products, then, are the *synchronization* between the actors (trucks and distributors).

If the resources are not available when the agents need them, the agents *block*. The agents cannot schedule any events until they become unblocked. If there are several agents awaiting a resource, we can implement whatever policy we want for who gets the resource next. Typically, we implement a "first-come, first-served" policy. That is where a *queue* enters into the situation. Blocked agents awaiting a resource wait in a queue,

and when a resource becomes available, the first agent in the queue gets the resource.

17.3 Different Kinds of Random

When you first start using Math.random(), you probably just think of getting a *random* number. What you might not think about is that there are different *kinds* of random.

- Are the numbers real (with a decimal point) or integer?
- From what range are the numbers drawn? For Math.random(), the range is $0.0 - -1.0$. For lottery tickets, the random numbers are usually in a much more well-defined range, like from $0 - -42$, with no real numbers allowed.
- Are all numbers in that range equally likely?

Random Distributions in the World

That last issue is quite important. Math.random() uses a *uniform random distribution*. All values between 0.0 and 1.0 are equally likely. Actually, few things that you might want to measure in the real world have a uniform distribution.

- Imagine that you made a list of all the heights of any randomly selected group of people, such as the heights of people in your class. The smallest might be five foot tall, and the largest might be six foot four inches. A uniform distribution would suggest that there are just as many people at five foot, as at five foot one inch, as at five foot two inches, as at six foot three inches, and six foot four inches. In reality, we know that there are few people at either end of a range, and most of the people will be around the average height of the group. We call this a *normal distribution* or a *Gaussian distribution* (after the guy who first described it).

  A *normal probability distribution* describes what happens if you put all these people in a room, then asked them to come out, one-at-a-time, in any order. The heights of the people coming out of that room would range between five foot and six foot four. Most of them will be around average. If you knew the average height of people in that room, and then a bunch of six foot four people came out of the door, you would think that something was strange. You would expect that the height of the people emerging from the room would fill in a normal distribution.

- Let us consider a different distribution. From any random group of people, consider the number of people with some disease (like tuberculosis or lung cancer) and the amount of exposure to some disease

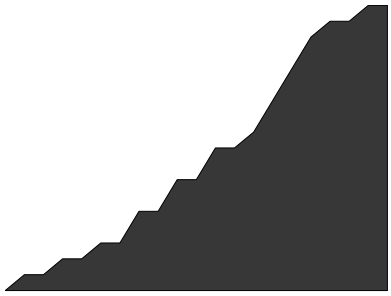

Figure 17.1: A distribution where there is only an increase

causing agent (like radiation or cigarette smoking). You would expect that very few people who have never smoked have lung cancer. (In fact, lung cancer was virtually unknown, except among miners, before smoking became widespread.) As you consider people who have smoked more and more, you expect the number of people who have lung cancer to also rise. Then number of lung cancer cases as the amount of smoking increases only increases—it never drops (Figure 17.1). It is not the case that one's doctor ever says, "Okay, your risk for lung cancer is really high now, but if you only smoke *a little bit more*, your risk of lung cancer will drop."

Our cigarette-to-cancer relationship might be an example of a *Poisson distribution* (again, after the guy who first described it). It depends on how the cigarettes and lung cancer relationship progresses. If it's a *linear* relationship, then the difference in number of cancer cases between two and four packs of cigarettes per day should be about the same as four and six packs of cigarettes per day, However, if the relationship between the variables changes much more quickly than that (e.g., on an exponential curve), then it may be a Poisson distribution.

Imagine that we have a hat, on which we have thrown pieces of paper, each with two numbers written on it: the number of cigarettes smoked (on average) per day, and the number of people who have lung cancer (from the group we randomly selected) who smoked that much. As we pull numbers out of the hat, we expect that a larger first number will also have a correspondingly large second number. If all the second numbers were the same, that would be a uniform distribution, and we would find that odd. If we found that the second numbers seem to cluster around an average value, then start to *decrease* while the first number gets even larger, that would be a normal distribution, and we would not expect that either.

Generating Different Random Distributions

A Problem and Its Solution: Understanding features, creating tools

No one understands everything about a set of programming libraries just from reading the descriptions. Sometimes, you can find examples to help you understand the libraries. Sometimes, you have to try it yourself. That's what we're going to do in this section—create small classes to generate some sample data, in order to better understand Random. It's okay that the class names aren't great, and that the classes don't integrate into a larger hierarchy of classes. It's a bit of code to help with understanding.

Further, we are going to need to generate some histograms to understand the data we're generating. We need a little tool to go from the data we'll be generating to the graphics that we want to see. Again, the code we generate will be small, and not necessarily well-engineered (e.g., with well-chosen classes names that integrate into a larger class hierarchy). Sometimes, you just need a tool, and you should feel free to build one.

There are lots of different kinds of relationships between two different variables: increasing, decreasing, uniform, curved increasing, curved decresing, S-shaped, and so on. The most common distributions that one deals with in a simulation are normal and uniform. Those two are built-in to the Random class that we have been using in this book.

- When we ask an instance of Random to provide a nextFloat(), we will get a random number between 0.0 and 1.0 drawn from a uniform probability distribution—all values are equally likely.
- When we ask an instance of Random to provide a nextGaussian(), we will get a random **float** number drawn from a normal probability distribution. The average value is 0.0 and a *standard deviation* of 1.0. The standard deviation describes the *spread* of the normal distribution "hill." If the standard deviation is small, then the hill is tall and spikey. If the standard deviation is large, then the values spread out more, and the hill is more like a rise along a flat plane. In any case, the majority of values in the hill fall between the mean value *minus* the standard deviation (-1.0 in the nextGaussian() distribution) and the mean value *plus* the standard deviation (1.0 for nextGaussian()). The spread of the distribution doesn't mean that -5.25 and 7.8 are *impossible*—they are just quite unlikely.

The textual description above might be clearer with some images. Let's generate a bunch of random numbers from each of these two distributions, then generate *histogram*s from the numbers—we'll count the number in each of various ranges (*bins*) in order to see how likely the different ranges

are from the distributions. First, let's generate 500 random numbers from a uniform distribution.

Example Java Code: **Generating random numbers from a uniform distribution** *Program Example #140*

```
import java.util.*;  // Need this for Random
import java.io.*;  // For BufferedWriter

public class GenerateUniform {
  public static void main(String[] args) {
    Random rng = new Random(); // Random Number Generator
    BufferedWriter output=null; // file for writing

   // Try to open the file
    try {
      // create a writer
      output =
        new BufferedWriter(new FileWriter("D:/cs1316/uniform.txt"));
    } catch (Exception ex) {
      System.out.println("Trouble opening the file.");
    }
      // Fill it with 5000 numbers between 0.0 and 1.0, uniformly distributed
      for (int i=0; i < 5000; i++){
        try{
        output.write("\t"+rng.nextFloat());
        output.newLine();
      } catch (Exception ex) {
        System.out.println("Couldn't write the data!");
        System.out.println(ex.getMessage());
        }
      }
      // Close the file
       try{
        output.close();}
      catch (Exception ex)
      {System.out.println("Something went wrong closing the file");}
}
}
```

How it works: This class is another example of creating a class just to have a main method that does what we need. We create a file writing stream on some file. In a loop for 5000 times, we get a random nextFloat and write it out the file. (By writing out a tab character first, we force string conversion, and thus avoid having to deal with conversions ourselves.) We

have the requisite **try**–**catch** to deal with possible file errors.

Now we want to figure out the number of random values that fall within each of 0.0 to 0.1, then 0.1 to 0.2, then 0.2 to 0.3, up to 1.0. Below is a program that reads in all random values generated by the above program, then generates a new file with the bins and the count of the number of values in that bin.

Program Example #141

Example Java Code: **Generate a histogram**

```
#I run this with: generateHistogram("/home/guzdial/uniform.txt","/home/guzdial/histo
def generateHistogram(infile,outfile,ranges):
  # infile is where the data is, one number per line
  # outfile will be right-value-of-range+tab+count-in-bin
  # ranges will be a list of bin high values, e.g., [0,.1,.2,.3,.4,.5]
  input = open(infile,"rt")
  output = open(outfile,"wt")
  numbers = input.readlines()
  input.close()
  histogram = {}  #histogram is a hash table
  # Clear the histogram
  for bin in ranges:
    histogram[bin] = 0
  #Now, count the values
  for numstr in numbers:
    num=float(numstr)
    for bin in ranges:
      found = 0
      if (num <= bin):
        # If num is in bin, increment corresponding hash
        histogram[bin] += 1
        found=1
        break
    if not found:
      #Put it in last bin
      histogram[ranges[-1]] += 1
  # Write out the values
  for bin in ranges:
    output.write(str(bin)+"\t"+str(histogram[bin])+"\n")
  output.close()
```

The file that this generates lists the bin size in one column, and the number of random values in that bin in the second column. That's a perfect form for generating a chart in any spreadsheet program. So, now we can take a look at the histogram for these 5000 uniform values (Figure 17.2).

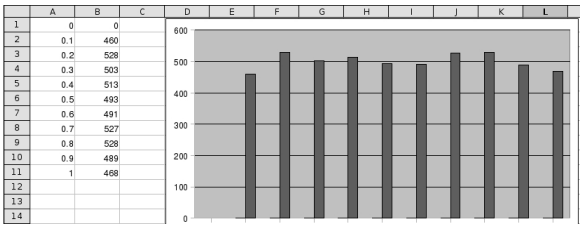

Figure 17.2: A histogram of 5000 random values from a uniform distribution

Yes, that looks pretty amazingly flat and uniform.

Now, let's do the same thing with our Gaussian, normal distribution.

Example Java Code: **Generate normal random variables**

Program Example #142

```
import java.util.*;  // Need this for Random
import java.io.*;  // For BufferedWriter

public class GenerateUniform {

  public static void main(String[] args) {
    Random rng = new Random(); // Random Number Generator
    BufferedWriter output=null; // file for writing

   // Try to open the file
    try {
      // create a writer
      output =
        new BufferedWriter(new FileWriter("/home/guzdial/uniform.txt"));
    } catch (Exception ex) {
      System.out.println("Trouble opening the file.");
    }

      // Fill it with 5000 numbers between 0.0 and 1.0, uniformly distributed
      for (int i=0; i < 5000; i++){
        try{
        output.write("\t"+rng.nextFloat());
        output.newLine();
      } catch (Exception ex) {
        System.out.println("Couldn't write the data!");
        System.out.println(ex.getMessage());
        }
      }

      // Close the file
```

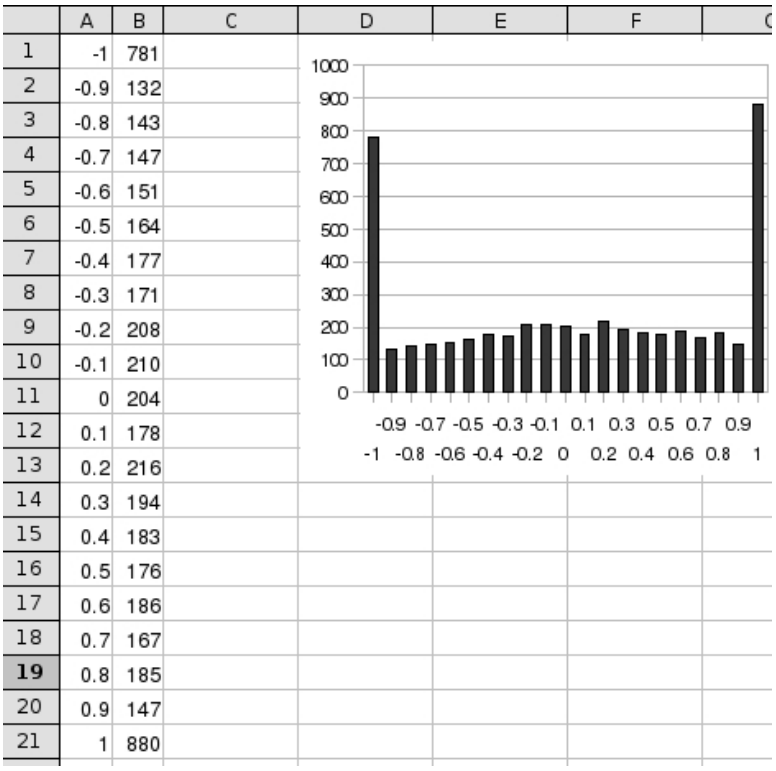

Figure 17.3: Our histogram of 5000 normal random values

```
        try{
          output.close();}
        catch (Exception ex)
        {System.out.println("Something went wrong closing the file");}
}
}
```

Again, we generate the histogram, now with bins from -1.0 to 1.0, since that's the range of the standard deviation of the built-in normal distribution in Random. When we graph it, we see the bell-shaped curve that we associate with a normal distribution (Figure 17.3)—except for those weird spikes on either end of the histogram! What are those? Recall that *most* of the values are between the mean $+/-$ the standard deviation. There are values lower than that, and higher than that. Those appear in the leftmost

and rightmost bins in our histograms.

Generating Useful Random Distributions

We hope that we have now convinced you that uniform and normal distributions *are* different kinds of random, and that we have shown you how to generate each from Random. The next step is to figure out how to make each of these useful. We will be using these random numbers to represent real values in the world, like height of a person or probability of developing cancer. Few of these values will be uniform between 0 and 1, or will be normally distributed with a mean of 0 and a standard deviation of 1.0.

We have already seen how to generate uniform random distributions in a certain range.

- You simply add the lower bound of what you want to the value returned from nextFloat(). If you want values to start at 4.0 for the variable that you are modeling, then adding 4.0 to nextFloat() gives you a value between 4.0 and 5.0.
- You multiply nextFloat() by the maximum size of the *range* of what you want. Let's say that you want values between 4.0 and 6.0. Your range is then 2.0 (6.0 − 4.0). 2.0∗nextFloat() will give you a value between 0.0 and 2.0. Add that to 4.0, e.g., 4.0∗(2.0∗rng.nextFloat()), and now you get a random value between 4.0 and 6.0.

The process is *exactly* the same for normal random distributions. You add the *mean* value, and multiply by the desired *standard deviation* to get the right *range*. In code, that is (range ∗ rng.nextGaussian()+mean). Let us test that, by generating a new normal random distribution, where we specify the mean and range.

Example Java Code: **Generating a specific normal random distribution** *Program Example #143*

```
import java.util.*;  // Need this for Random
import java.io.*;  // For BufferedWriter

public class GenerateNewNormal {

  public static void main(String[] args) {
    Random rng = new Random(); // Random Number Generator
    BufferedWriter output=null; // file for writing

    double mean = 25.0;
    double range = 5.0;
   // Try to open the file
    try {
```

```
      // create a writer
      output =
        new BufferedWriter(new FileWriter("/home/guzdial/normal-new.txt"));
    } catch (Exception ex) {
      System.out.println("Trouble opening the file.");
    }

    // Fill it with 500 numbers with a mean of 25.0 and a
    //larger spread, normally distributed
      for (int i=0; i < 500; i++){
        try{
        output.write("\t"+((range * rng.nextGaussian())+mean));
        output.newLine();
      } catch (Exception ex) {
        System.out.println("Couldn't write the data!");
        System.out.println(ex.getMessage());
        }
      }

      // Close the file
       try{
        output.close();}
      catch (Exception ex)
      {System.out.println("Something went wrong closing the file");}
}
}
```

When we generate the histogram via our bin-counting program and spreadsheet, we see that we do get a fairly normal curve, with a mean of 25.0 and with most of the values between 20.0 and 30.0 (Figure 17.4).

17.4 Straightening Time

As we mentioned at the start of this chapter, it is important to keep time straight in a discrete event simulation. Since we do not generate every moment in time, we use our random distributions to come up with realistic lengths of time between events. In our simulation, we might have a moment where Truck A leaves the factory on day 3.0, going on a trip that averages 2.5 days, with a standard deviation of 0.5 days. Rather than simulate the $2.5 + / - 0.5$ days, we roll our random die, and might find that this truck will take 3.2 days. (It happens.) We queue up Truck A to arrive on day 6.2 (call it "early in the morning on day 6"). Now, Truck B leaves on day 3.5 and the random die comes out as 2.0. We queue up Truck B to arrive on day 5.5. "But wait!" you say. "Using a normal queue means that Truck B comes *after* Truck A!"

You are right. According to the order of time, Truck B passes Truck A somewhere on the road and shows up a day before. How do we fix it so that

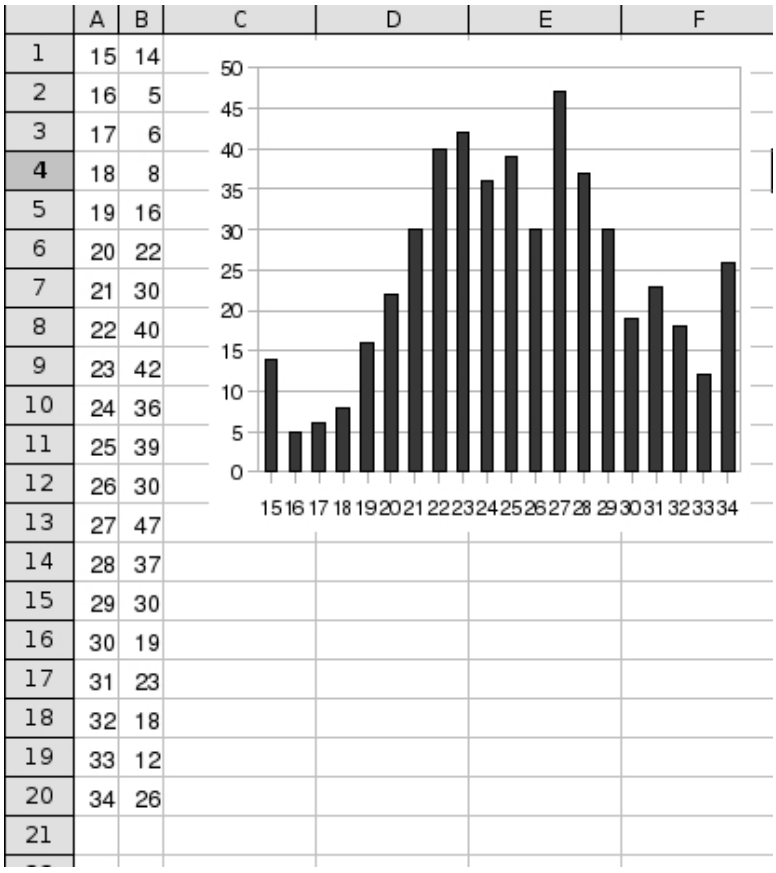

Figure 17.4: Histogram drawn from a normal distribution to our specifications

we process the trucks in the order in which they are supposed to arrive, not in the actual order in which they arrived in our processing queue?

The goal is that the elements in the queue should always be in *sorted order*. The elements at the front of the queue should have smaller event times than those later in the queue. Then, when we process the first element in the queue, we are sure to have the *next* (earliest) event being processed. There are two ways to achieve this goal:

- We can *sort* the queue after each element arrives. Sorting involves putting all the elements in the right order.
- We can *insert* the new element into the queue in *sorted order*, so that the queue is *always* in the right order.

Let's set up the problem as a program, first, then try each of our solu-

tions. Let us set up an event queue exerciser—something we can use to test our event queue implementations, both versions. Our exerciser creates a bunch of events, in the *wrong* order (e.g., not always increasing), then pulls them back out. Our goal is to get them back out in sorted order.

Program Example #144

Example Java Code: **Event Queue Exerciser**

```
public class EventQueueExercisor {
  public static void main(String[] args){
    // Make an EventQueue
    EventQueue queue = new EventQueue();

    // Now, stuff it full of events, out of order.
    SimEvent event = new SimEvent();
    event.setTime(5.0);
    queue.add(event);

    event = new SimEvent();
    event.setTime(2.0);
    queue.add(event);

    event = new SimEvent();
    event.setTime(7.0);
    queue.add(event);

    event = new SimEvent();
    event.setTime(0.5);
    queue.add(event);

    event = new SimEvent();
    event.setTime(1.0);
    queue.add(event);

    // Get the events back, hopefull in order!
    for (int i=0; i < 5; i++) {
      event = queue.pop();
      System.out.println("Popped event time:"+event.getTime());
    }
  }
}
```

How it works: There's not much to this code. As you can see, we are using SimEvent, an instance of which represents a simulation event. We will see how that is implemented, in just a few pages. In the exerciser, we create some SimEvent instancs, out of time order, and add them to the

EventQueue instance. Then we pop them off. If we do it right, we should see this:

```
Welcome to DrJava.
> java EventQueueExercisor
Popped event time:0.5
Popped event time:1.0
Popped event time:2.0
Popped event time:5.0
Popped event time:7.0
```

Now, let's start our event queue implementation.

Example Java Code: **EventQueue (start)** *Program Example #145*

```
import java.util.*;

/**
 * EventQueue
 * It's called an event "queue," but it's not really.
 * Instead, it's a list (could be an array, could be a linked list)
 * that always keeps its elements in time sorted order.
 * When you get the nextEvent, you KNOW that it's the one
 * with the lowest time in the EventQueue
 **/
public class EventQueue {
  private LinkedList elements;

  /// Constructor
  public EventQueue(){
    elements = new LinkedList();
  }
 public SimEvent peek(){
    return (SimEvent) elements.getFirst();}

  public SimEvent pop(){
    SimEvent toReturn = this.peek();
    elements.removeFirst();
    return toReturn;}

  public int size(){return elements.size();}

  public boolean empty(){return this.size()==0;}

  /**
   * Add the event.
   * The Queue MUST remain in order, from lowest time to highest.
   **/
  public void add(SimEvent myEvent){
```

```
// Option one: Add then sort
elements.add(myEvent);
this.sort();
//Option two: Insert into order
//this.insertInOrder(myEvent);
}
```

How it works: An EventQueue is like a code only in the sense that, all times being equal, it will insert at the end and pull from the front. Most of the methods, like pop() and peek(), are the same as in our previous Queue implementations. The tricky part of add(). First, we'll explore the first option: Doing a normal add(), then sorting the events.

Sorting Time

Placing a collection of items in order has been a task that computer scientists have explored for a long time. It's trickier than one might think. There are lots of ways to do it, and many are smarter (and thus, faster) than others. The obvious but incorrect ones take $O(n^2)$ time—if there are n elements in the collection to be sorted, it takes (roughly) n^2 steps to sort the collection. The best ones take $O(n * log_2(n))$ steps to do it.

These are not difficult to make sense of. Let's think it through:

- Here's a simple method of sorting a collection of items. Let's say that you want the smallest item in the collection to be at the front. You pick up the first item in the collection and then compare it to every other item in the list. If you find one of them to be smaller than the one you're holding, you put the one you're holding in its spot and hold the other one. When you get to the end, you go back and pick up the second item, and compare it to every other one. Eventually, you should see that the whole collection becomes sorted. Since every single one of the n items gets compared to every single other one of the n items, there are $n * n$ comparisons made—$O(n^2)$.
- Here's a different way of thinking about the fastest way to do it. Remember when we talked about searches in trees, and pointed out that the fastest search is $O(log_2(n))$? Imagine if you could take each of the n items, then search out the right place to put it in $log_2(n)$ steps. The end result is that you would do the whole sort in $n * log_2(n)$ steps—$O(n * log_2(n))$.

There are also sorts that are better than $O(n^2)$ in some cases, but in the *worst case analysis* is just that bad. We are going to implement one of those to do our sort. We are going to implement an insertion sort. The basic idea of an insertion sort is the first method that we described above—you slowly grow the part that is sorted as you go along. Here's how an insertion sort works:

- Consider the event at some position, from $(1..n)$.
- Compare it to all the events before that position backwards—towards index zero, the front of the array.
  - If the comparison event time is *less than* the time in the event we're considering, then shift the comparison event down to make room.
  - Wherever we stop with this process of comparing and shifting, thats where the considered event goes. Once the comparison event is greater than or equal to the considered event—stop.
- Now consider the next event from $(1..n)$, until done.

Here's the code, for EventQueue, that implements this.

Example Java Code: **Insertion Sort for EventQueue**

Program Example #146

```
public void sort(){
   // Perform an insertion sort

   // For comparing to elements at smaller indices
   SimEvent considered = null;
   SimEvent compareEvent = null; // Just for use in loop
   // Smaller index we're comparing to
   int compare;

   // Start out assuming that position 0 is "sorted"
   // When position==1, compare elements at indices 0 and 1
   // When position==2, compare at indices 0, 1, and 2, etc.
   for (int position=1; position < elements.size(); position++){
     considered = (SimEvent) elements.get(position);
     // Now, we look at "considered" versus the elements
     // less than "compare"
     compare = position;

     // While the considered event is greater than the compared event ,
     // it's in the wrong place, so move the elements up one.
     compareEvent = (SimEvent) elements.get(compare-1);
     while (compareEvent.getTime() >
            considered.getTime())  {
       elements.set(compare,elements.get(compare-1));
       compare = compare-1;
       // If we get to the end of the array, stop
       if (compare <= 0) {break;}
       // else get ready for the next time through the loop
       else {compareEvent = (SimEvent) elements.get(compare-1);}
```

```
      }
      // Wherever we stopped, this is where "considered" belongs
      elements.set(compare,considered);
    } // for all positions 1 to the end
  } // end of sort()
```

If all the events are in sorted order already, we consider each of the n elements, compare them to only the next element and then stop. Since each element is only being compared to one other, it is *in the best case* $O(n)$. However, we cannot be sure of that—in fact, the best case is quite unlikely. If the collection is *exactly sorted in reverse order* (e.g., largest one is at the front), then every one of the n elements gets compared to every other of the n elements—in the *worst case*, the insertion sort is $O(n^2)$.

Inserting into Sorted Time

If after every time we add an event, we then sort it, we can be sure that the event queue remains in sorted order. However, this is a particularly time-consuming (dumb) way of doing it. We *know* that the only new element in the queue, that needs to be put into the right order, is the single new one. Think about it this way: You are holding a collection of numbered cards, which you have in an order from smallest-to-largest. Someone hands you a new card. Do you put it at the end, then re-sort the whole deck? Of course not! Instead, you take the new card, and figure out where it fits into your hand. That is , and it is much more efficient than sorting after every addition.

In order to try this new approach, we're considering this other option for EventQueue's add():

```
/**
 * Add the event.
 * The Queue MUST remain in order, from lowest time to highest.
 **/
public void add(SimEvent myEvent){
// Option one: Add then sort
//elements.add(myEvent);
//this.sort();
//Option two: Insert into order
this.insertInOrder(myEvent);
}
```

Inserting into an ordered list is much simpler. We simply figure out where something goes, then move (shift) the array down to make room.

Program Example #147

Example Java Code: **Inserting into a sorted order (EventQueue)**

```
/**
  * Put thisEvent into elements, assuming
  * that it's already in order.
  **/
 public void insertInOrder(SimEvent thisEvent){
   SimEvent comparison = null;

   // Have we inserted yet?
   boolean inserted = false;
   for (int i=0; i < elements.size(); i++){
     comparison = (SimEvent) elements.get(i);

     // Assume elements from 0..i are less than thisEvent
     // If the element time is GREATER, insert here and
     // shift the rest down
     if (thisEvent.getTime() < comparison.getTime()) {
       //Insert it here
       inserted = true;
       elements.add(i,thisEvent);
       break; // We can stop the search loop
     }
   } // end for

   // Did we get through the list without finding something
   // greater? Must be greater than any currently there!
   if (!inserted) {
     // Insert it at the end
     elements.addLast(thisEvent);}
 }
```

17.5 Implementing a Discrete Event Simulation

At this point, we know all that we need to implement a discrete event simulation. This is a big project using many of the data structures that we have learned about in this book, such as:

- Queues: For storing the agents waiting in line.
- EventQueues: For storing the events scheduled to occur.
- LinkedList: For storing all the agents.

We will run our discrete event simulation like this:

```
Welcome to DrJava.
> FactorySimulation fs = new FactorySimulation();
> fs.openFrames("D:/temp/");
> fs.run(25.0)
```

Figure 17.5: Screenshot of factory simulation running

When we run the simulation, we will see a screen like Figure 17.5. The turtles (representing agents) do not move from place-to-place in this figure. They simply appear in each of the locations: At the factory, at the warehouse, at the start of the marketplace, and leaving the marketplace. Since we do not simulate the moments in between these discrete events, we do not see the motion that would (in the real world) occur between those moments. Basically, the animation is not very useful in the discrete event simulation.

All the useful information coming out of a discrete event simulation is in the details, either stored to a file or appearing in the console. For example, here are some lines from the console during a run of the factory simulation:

```
Time:        1.7078547183397625        Distributor: 0         Arrived at warehouse
Time:        1.7078547183397625        Distributor: 0         is blocking
>>> Timestep: 1
Time:        1.727166341118611        Distributor: 3         Arrived at warehouse
Time:        1.727166341118611        Distributor: 3         is blocking
>>> Timestep: 1
Time:        1.8778754913001443        Distributor: 4         Arrived at warehouse
Time:        1.8778754913001443        Distributor: 4         is blocking
>>> Timestep: 1
Time:        1.889475045031698        Distributor: 2         Arrived at warehouse
Time:        1.889475045031698        Distributor: 2         is blocking
>>> Timestep: 1
```

```
Time:        3.064560375192933       Distributor: 1         Arrived at warehouse
Time:        3.064560375192933       Distributor: 1         is blocking
>>> Timestep: 3
Time:        3.444420374970288       Truck: 2         Arrived at warehouse with load
Time:        3.444420374970288       Distributor: 0         unblocked!
Time:        3.444420374970288       Distributor: 0         Gathered product for orders of
>>> Timestep: 3
Time:        3.8869697922832698       Truck: 0         Arrived at warehouse with load
Time:        3.8869697922832698       Distributor: 3         unblocked!
Time:        3.8869697922832698       Distributor: 3         Gathered product for orders of
>>> Timestep: 3
Time:        4.095930381479024       Distributor: 0         Arrived at market
>>> Timestep: 4
Time:        4.572840072576855       Truck: 1         Arrived at warehouse with load
Time:        4.572840072576855       Distributor: 4         unblocked!
Time:        4.572840072576855       Distributor: 4         Gathered product for orders of
```

Let's spell this out a bit, to explain what's happening here:

- The first Distributor (number 0) appears at the warehouse at time 1.7 (call it "late on the first day of the simulation.") There is nothing in the warehouse yet, because no trucks have arrived, so the distributor blocks, waiting.
- Moments later, Distributor 3 appears. What happened to Distributors 1 and 2? In the real world, it might be traffic or car trouble. In terms of the simulation implementation, the variance in the random distribution led to Distributor 3 showing up before 1 and 2.
- Distributors 4 and 2 arrive slightly thereafter. Still no trucks, so everyone is blocked waiting.
- Distributor 1 arives at time 3.0. Notice that day 2 (time 2.0) never happens in the simulation—no significant event occurs on the second day, so we never simulate it. (Distributor 1 must have run into real trouble that it took him a whole extra day to arrive at the warehouse!)
- Finally, at time 3.4, Truck 2 arrives. (Trucks 0 and 1 were still stuck out on the road.) Truck 2 had 13 boxes. Distributor 0 had orders for 11 boxes, so she gets those 11 boxes and leaves. That leaves 2 boxes in the warehouse, which isn't enough for Distributor 3 (the next in the queue) to fill his orders.
- Truck 0 arrives at 3.8 with 18 more boxes. That's enough for Distributor 3 to collect the 12 that he needs, so he's off.
- At time 4.0, Distributor 0 arrives at the market to start delivering her products.
- Meanwhile, back at the warehouse at time 4.5, Truck 1 finally gets there with 20 more boxes, and Distributor 4 can unblock and be off.

- And so on...

Once you have a simulation like this for any real situation that you might want to model, and you are convinced that the model is pretty accurate, there are lots of questions that you can ask which might be hard to answer in the real world.

- How long do distributors wait? If we recorded the time when the block (get stuck in line), then when they unblock, we could get the difference and write it to a file. We could then average those differences to get a sense of the lost time while the distributors wait.

- How much product sits in the warehouse? Given the above snippet of the simulation, we get the idea that the warehouse does not have to store much at any time. Maybe we need more of a backroom than a whole warehouse? We could compute the maximum amount of product being stored by simply computing the amount in the warehouse at each time a distributor leaves, then writing it out for analysis after the execution.

- How long does the queue of distributors get at the warehouse? Just how many of our salespeople are hanging out the local Motel 6 awaiting trucks? Each time that a distributor blocks, we could save the number of people in the queue.

- Finally, the most interesting question for the owners of the system, Can we move more product by having more distributors? Or more trucks? Or maybe bigger or faster trucks? We can easily make these changes and see what happens.

Building a Discrete Event Simulation

Figure 17.6 is a UML class diagram describing the classes in our discrete event simulation package. You see that these are an extension of the simulation package classes we have created previously.

- Class DESimulation represents a Discrete Event Simulation, which is an extension of Simulation. An instance of DESimulation has a field for now, which always stores the time off the latest event pulled from the EventQueue referenced by the field events. A DESimulation has a different kind of run(), one that takes a floating point value as the stopping time, and stops when now goes past the input time.

- A DEAgent represents an agent in a discrete event simulation, which is an extension of Agent. An instance of DEAgent knows if it is blocked (e.g., waiting in a queue), and it has a set of methods that can be queried to determine if the agent isBlocked() or isReady() (to execute

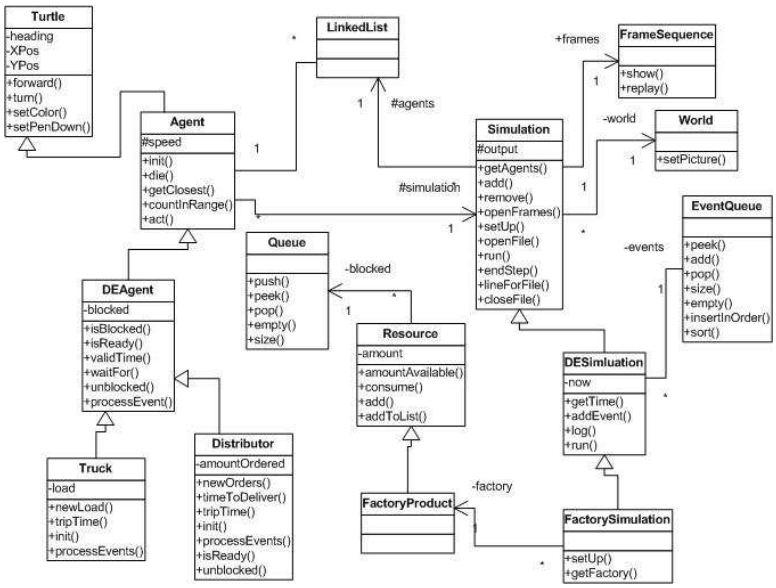

Figure 17.6: UML class diagram of the discrete event simulation package

again). An instance of DEAgent will waitFor() some resource, then become unblocked() and will likely then processEvent(). Processing events is actually the main activity of DEAgent instances, rather than act().

- There is also a class Resource that represents some resource that the agents want, produce, or consume in a discrete event simulation. A Resource instance has a field blocked which points to an instance of a Queue for storing blocked agents. Agents are blocked by calling addToList() on that resource. A Resource instance knows how to tell the amountAvailable() of itself, and can be told to consume() that resource or add() to that resource.

Figure 17.7 extends the earlier class diagram with the classes needed to implement our factory simulation. There are only four new classes.

- The class FactorySimulation extends DESimulation. It defines its own setUp() method, and it knows how to getFactory().
- The factory is just a reference to a FactoryProduct class which extends Resource—but that's all it is. (It doesn't need to be there at all—it just allows us to talk about "Factory Products" rather than "Resources.")
- The Distributor class defines what distributors do, as a subclass of DEAgent. An instance of Distributor has its own init(), processEvents(), isReady(), and unblocked(). Its methods newOrders(), timeToDeliver(), and tripTime() use random distributions to generate (respectively) the

Figure 17.7: UML class diagram with factory simulation classes

number of new orders taken, the time to deliver product, and the time to travel between the marketplace and the warehouse.

- The Truck class defines what trucks do as a subclass of DEAgent. An instance of Truck has its own init() and processEvents(), but not the others that Distributor overrides since trucks never block. A Truck does know how to compute its newLoad() (from the factory) and tripTime() (between the factory and warehouse).

The heart of any discrete event simulation in this package is the subclass of DESimulation. A DESimulation instance:

- Calls setUp() to create agents and schedule the first events.
- Provides log() for writing things out to the console and a text file.
- Executes run() by processing each event in the event queue and tells the corresponding agent to process a particular message.

Here is the heart of the run() method in DESimulation:

```
// While we're not yet at the stop time,
   // and there are more events to process
   while ((now < stopTime) && (!events.empty())) {
     topEvent = events.pop();

     // Whatever event is next, that time is now
     now = topEvent.getTime();
     // Let the agent now that its event has occurred
     topAgent = topEvent.getAgent();
     topAgent.processEvent(topEvent.getMessage());

     // repaint the world to show the movement
     // IF there is a world
     if (world != null) {
       world.repaint();}

     // Do the end of step processing
     this.endStep((int) now);
   }
```

How it works: This section of code reads pretty close to our definition of how a discrete event simulation works. As long as there are events in the queue, and were not at the time to stop, we (1) grab an event from the event queue, (2) make the new event's time "now," (3) process the event. The repainting of the world and end-of-step processing are details to the main event.

You may be wondering what our SimEvent instances look like. There really isn't much to them.

Example Java Code: **SimEvent (just the fields)**

Program Example #148

```
/**
 * SimulationEvent (SimEvent) -- an event that occurs in a simulation,
 * like a truck arriving at a factory, or a salesperson leaving the
 * market
 **/
public class SimEvent{
  /// Fields ///
  /** When does this event occur? */
  public double time;

  /** To whom does it occur? Who should be informed when it occurred? */
  public DEAgent whom;

  /** What is the event? We'll use integers to represent the meaning
   * of the event -- the "message" of the event.
   * Each agent will know the meaning of the integer for themselves.
   **/
  public int message;
```

How it works: An instance of SimEvent consists of a time when the event should occur, an instance of DEAgent describing to whom the event should occur, and an integer message which should have meaning to the agent. That message will be sent to the agent, who will know the meaning of the number that is that message. It could be a string, or just about anything—we simply decided to model it as a number.

All action within the simulation occurs within DEAgent as it processes events. The subclasses of DEAgent define the constant numbers for messages, in answer to the question "What will be the main events for this agent?" If an agent needs a resource, it asks to see if it's available, and if not, it blocks itself. It will be told to unblock when its ready. The most critical aspect of any DEAgent is that each agent is responsible for scheduling its own events. The DESimulation class doesn't decide when agents

come and go—the agents themselves cause their next activity to occur by creating the appropriate events and pushing them onto the event queue.

Let's take the Truck class as an example of a kind of DEAgent.

Program Example #149

Example Java Code: **Truck**

```
import java.awt.Color; // For color

/**
 * Truck -- delivers product from Factory
 * to Warehouse.
 **/
public class Truck extends DEAgent {

  /////// Constants for Messages
  public static final int FACTORY_ARRIVE = 0;
  public static final int WAREHOUSE_ARRIVE = 1;

  ////// Fields /////
  /**
   * Amount of product being carried
   **/
  public int load;

  //// METHODS ///
  /** A new load is between 10 and 20 on a uniform distribution */
  public int newLoad(){
    return 10+randNumGen.nextInt(11);
  }

  /** A trip distance averages 3 days */
  public double tripTime(){
    double delay = randNumGen.nextGaussian()+3;
    if (delay < 1)
      // Must take at least one day
    {return 1+((DESimulation) simulation).getTime();}
    else {return delay+((DESimulation) simulation).getTime();}
  }
  /**
   * Set up the truck
   * Start out at the factory
   **/
  public void init(Simulation thisSim){
    // Do the default init
    super.init(thisSim);
    this.setPenDown(false); // Pen up
    this.setBodyColor(Color.green); // Let green deliver!
```

```
    // Show the truck at the factory
    this.moveTo(30,350);
    // Load up at the factory, and set off for the warehouse
    load = this.newLoad();
    ((DESimulation) thisSim).addEvent(
              new SimEvent(this,tripTime(),WAREHOUSE_ARRIVE));
  }

  /**
   * Process an event.
   * Default is to do nothing with it.
   **/
  public void processEvent(int message){
    switch(message){
      case FACTORY_ARRIVE:
        // Show the truck at the factory
        ((DESimulation) simulation).log(this.getName()+"\t Arrived at factory");
        this.moveTo(30,350);
        // Load up at the factory, and set off for the warehouse
        load = this.newLoad();
        ((DESimulation) simulation).addEvent(
              new SimEvent(this,tripTime(),WAREHOUSE_ARRIVE));
        break;
      case WAREHOUSE_ARRIVE:
        // Show the truck at the warehouse
        ((DESimulation) simulation).log(this.getName()+"\t Arrived at warehouse with load \t"+
        this.moveTo(50,50);
        // Unload product -- takes zero time (unrealistic!)
        ((FactorySimulation) simulation).getFactory().add(load);
        load = 0;
        // Head back to factory
        ((DESimulation) simulation).addEvent(
              new SimEvent(this,tripTime(),FACTORY_ARRIVE));
        break;
    }
  }

  ////////////////////////////// Constructors ////////////////////////
  // Skipping them here
}
```

How it works: The Truck class has two constants representing event messages: one for arriving at the factory, and the other for arriving at the warehouse. The only other field of a Truck is its load.

- The init() method sets up the truck. A bunch of housekeeping is done for the sake of the graphical representation (e.g., setting body color,

and moving the turtle), but those are really pretty unimportant. The important part is that every truck gets an initial load (newLoad()), and then schedules itself to arrive at the warehouse. Let's take apart that line a little bit.

```
((DESimulation) thisSim).addEvent(
            new SimEvent(this,tripTime(),WAREHOUSE_ARRIVE));
```

The simulation object is passed into init() as the parameter thisSim. We cast it to DESimulation in order to add an event (addEvent) to the event queue. We create a new simulation event (SimEvent), that speaks to **this** agent, is scheduled to occur at tripTime(), and whose event is "Arrive at the warehouse."

- The tripTime() method computes the delay as randNumGen.nextGaussian()+3—that makes it between 2.0 and 4.0 days to arrive. Now, while that is unlikely, it is possible for that number to be less than 1.0. We assume that it is possible to make the trip in one day (by speeding and avoiding all speed traps), so the trip time is the current time (((DESimulation) simulation).getTime()) plus the normally distributed delay *or* 1.0.
- A newLoad() is a simple uniform distribution, between 10 and 20.
- The method processEvent is called when a message is popped off the event queue for this agent. The agent is told to process, with the message number as input. We use a **switch** statement to choose what to do, based on the message input.
  - If we have just arrived at the factory, we log() that information and move the turtle. We then compute a new load, and move back to the warehouse.
  - Once we get to the warehouse, we log() that information and move the turtle. We then ask the factory to accept our product: ((FactorySimulation) simulation).getProduct().add(load); Note that there is actually a big flaw in the veracity of this part of the simulation: it takes no time to empty the truck. Wouldn't you expect the time to empty the truck to be a function of the size of the load? In any case, our truck now has nothing in it (load = 0;), so the truck schedules a new event to arrive back at the factory.

Instances of Resource They keep track of what amount they have available (of whatever the resource is). They maintain a queue of agents that are blocked on this resource. They can add to the resource, or have it consume(d). When more resource comes in, the agent at the head of the blocked queue gets asked if there is enough resource for it to continue, by asking it if it isReady(). If so, it can unblock. The code that does that last part looks like this:

```
/**
 * Add more produced resource.
 * Is there enough to unblock the first
 * Agent in the Queue?
 **/
public void add(int production) {
  amount = amount + production;

  if (!blocked.empty()){
    // Ask the next Agent in the queue if it can be unblocked
    DEAgent topOne = (DEAgent) blocked.peek();
    // Is it ready to run given this resource?
    if (topOne.isReady(this)) {
      // Remove it from the queue
      topOne = (DEAgent) blocked.pop();
      // And tell it it s unblocked
      topOne.unblocked(this);
    }
  }
}
```

Let's now look at the more complicated agent in our simulation, the Distributor, since it does block on resources.

Example Java Code: **Distributor**

Program Example #150

```
import java.awt.Color; // To color our distributors
/**
 * Distributor — takes orders from Market to Warehouse,
 * fills them, and returns with product.
 **/
public class Distributor extends DEAgent {

  /////// Constants for Messages
  public static final int MARKET_ARRIVE = 0;
  public static final int MARKET_LEAVE = 1;
  public static final int WAREHOUSE_ARRIVE = 2;

  /** AmountOrdered so-far */
  int amountOrdered;

  // Methods

  public int newOrders(){
    // Between 5 and 25, uniform
    return randNumGen.nextInt(21)+5;
  }
```

```
  public double timeToDeliver(){
    // On average 5 days to deliver, normal distr.
    return validTime(randNumGen.nextGaussian()+5);}

  public double tripTime(){
    // On average 2 days to travel between market and warehouse
    return validTime(randNumGen.nextGaussian()+2);}

  /**
   * Initialize a distributor.
   * Start in the market, taking orders, then
   * schedule arrival at the warehouse.
   **/
  public void init(Simulation thisSim){
    //First, do the normal stuff
    super.init(thisSim);
    this.setPenDown(false); // Pen up
    this.setBodyColor(Color.blue); // Go Blue!

    // Show the distributor in the market
    this.moveTo(600,460); // At far right
    // Get the orders, and set off for the warehouse
    amountOrdered = this.newOrders();
    ((DESimulation) thisSim).addEvent(
              new SimEvent(this,tripTime(),WAREHOUSE_ARRIVE));
  }

  /** Are we ready to be unlocked? */
  public boolean isReady(Resource res) {
    // Is the amount in the factory more than our orders?
    return ((FactorySimulation) simulation).getFactory().amountAvailable() >= amoun

  /**
   * I've been unblocked!
   * @param resource the desired resource
   **/
  public void unblocked(Resource resource){
    super.unblocked(resource);

    // Consume the resource for the orders
    ((DESimulation) simulation).log(this.getName()+"\t unblocked!");
    ((FactoryProduct) resource).consume(amountOrdered); // Zero time to load?
    ((DESimulation) simulation).log(this.getName()+"\t Gathered product for orders
    // Schedule myself to arrive at the Market
    ((DESimulation) simulation).addEvent(
              new SimEvent(this,tripTime(),MARKET_ARRIVE));
  }

  /**
   * Process an event.
```

```
   * Default is to do nothing with it.
   **/
  public void processEvent(int message){
      switch(message){
        case MARKET_ARRIVE:
          // Show the distributor at the market, far left
          ((DESimulation) simulation).log(this.getName()+"\t Arrived at market");
          this.moveTo(210,460);
          // Schedule time to deliver
          ((DESimulation) simulation).addEvent(
              new SimEvent(this,timeToDeliver(),MARKET_LEAVE));
          break;
        case MARKET_LEAVE:
          // Show the distributor at the market, far right
          ((DESimulation) simulation).log(this.getName()+"\t Leaving market");
          this.moveTo(600,460);
          // Get the orders, and set off for the warehouse
          amountOrdered = this.newOrders();
          ((DESimulation) simulation).addEvent(
              new SimEvent(this,tripTime(),WAREHOUSE_ARRIVE));
           break;
        case WAREHOUSE_ARRIVE:
          // Show the distributor at the warehouse
          ((DESimulation) simulation).log(this.getName()+"\t Arrived at warehouse");
          this.moveTo(600,50);
          // Is there enough product available?
          FactoryProduct factory = ((FactorySimulation) simulation).getFactory();
          if (factory.amountAvailable() >= amountOrdered)
          {
            // Consume the resource for the orders
            factory.consume(amountOrdered); // Zero time to load?
            ((DESimulation) simulation).log(this.getName()+"\t Gathered product for orders of
            // Schedule myself to arrive at the Market
            ((DESimulation) simulation).addEvent(
                    new SimEvent(this,tripTime(),MARKET_ARRIVE));
          }
          else {// We have to wait until more product arrives!
            ((DESimulation) simulation).log(this.getName()+"\t is blocking");
            waitFor(((FactorySimulation) simulation).getFactory());}
        break;
    }}

    ////////////////////////////// Constructors ///////////////////////
  // Skipping those here
}
```

How it works: The class Distributor has three kinds of messages: arriving at the warehouse, arriving at the market (where the distributor de-

livers product and collects new orders), and leaving the market. The only other field it has is amountOrdered.

- In the init() method, the Distributor instance is just leaving the market. It computes a number of newOrders() that it has just collected, and it schedules itself to arrive at the warehouse.
- There are three kinds of events to be handled in processEvent() for Distributor instances.
  - When arriving at the market, the distributor logs the activity and moves the turtle. The distributor then schedules the departure from the market.
  - When leaving the market, the amount of new orders is computed, and then arrival back at the warehouse is scheduled.
  - Here's where it gets more interesting. When the distributor gets to the warehouse, it asks how much product there is (((FactorySimulation) simulation).getPr then asks if there is enough product available to fill its orders. If so, the distributor consumes the product, logs the activity, then schedules the trip back to the market. If *there is not enough product*, the distributor blocks, waiting on the resource.
- The distributor isReady() to go on when there is enough product: ((FactorySimulation) simulation
- When the distributor is unblocked(), it consumes the product and schedules the trip back to the market.

After seeing all of this, the FactorySimulation itself does very little. Instead, it merely sets up the pieces and lets it all go.

Program Example #151

Example Java Code: **FactorSimulation**

```
/**
 * FactorySimulation -- set up the whole simulation,
 * including creation of the Trucks and Distributors.
 **/
public class FactorySimulation extends DESimulation {

  private FactoryProduct factory;

  /**
   * Accessor for factory
   **/
  public FactoryProduct getFactory(){return factory;}

  public void setUp(){
    // Let the world be setup
```

```
    super.setUp();
    // Give the world a reasonable background
    world.setPicture(new Picture(
                    FileChooser.getMediaPath("EconomyBackground.jpg")));

    // Create a factory resource
    factory = new FactoryProduct(); //Track factory product

    // Create three trucks
    Truck myTruck = null;
    for (int i=0; i<3; i++){
      myTruck = new Truck(world,this);
      myTruck.setName("Truck: "+i);}

    // Create five Distributors
    Distributor sales = null;
    for (int i=0; i<5; i++){
      sales = new Distributor(world,this);
      sales.setName("Distributor: "+i);}
  }
}
```

17.6 The Final Word: The Thin Line between Structure and Behavior

We have now completed an entire course on data structures. We have covered a lot of material about representing structure and behavior. Here are some of the things we have learned about data structures and their properties:

- **Arrays** are efficient in memory, since everything is packed together serially. They are very fast for accessing any individual element. They are hard to insert and delete with, since we have to compact and expand the memory space. Arrays, by their nature, cannot be grown—they have a fixed size.

- **Linked lists** are slightly less memory efficient, since every element has an additional piece of memory that points to the next element. They are wonderfully simple for allowing insertion and deletion—one merely disconnects and reconnects. Accessing any element is costly in terms of time. One basically has to search to find any element. Linked lists can expand as much as available memory allows.

- **Circular linked lists** are good for describing data that has a natural loop in it. However, be careful traversing them using normal methods, or one could end up in an infinite loop.

- **Trees** are terrific for describing data that has hierarchy or clustering to it. They are a form of linked lists that use branch nodes to connect to children, as well as a next element. In binary trees, *every* node is both data and branch, since every node encodes both a left and a right branch. Trees have the insertion and deletion, and expandability, strengths of linked lists. While a general tree also has to be searched to find things, trees can be structured to allow for faster access than a linked list.

- **Graphs** are like trees, but allow for arbitrary linking. Any node can link to any other node, allowing for looping. Graphs are great for representing structures that do loop, like transit systems and pipes and blood paths.

- **Stacks** are last-in-first-out (LIFO) lists. We defined them using an Abstract Data Type (ADT). Our use for stacks was reversing a list.

- **Queues** are first-in-first-out (FIFO) lists. Our use for queues was for representing agents awaiting a resource.

Let's step back a little. This book uses Java as its language for implementation and description. Java is an *object-oriented language*, which means that it is structured around *objects*. Objects have fields and methods. They specify both structure (of data, through fields) and behavior (process, through methods). They combine both of these ideas in a single computational entity. Each instance of a class has all the data structures of the class and all the behaviors of the class.

Objects are not the only computational entities that combine structure and behavior. In fact, several of the data structures that we built in this book combine structure and behavior in fairly complex ways. Consider the branches in our trees that scale (for sounds) or move or horizontally/vertically place other pictures. Rendering of those sound trees or image trees was changed based on where those special scaling or moving branches were in the tree. The resultant sound or image was dependent upon the structure of the tree that created it. The *behavior* was determined, in part, by the *structure* of the data. Or, consider the integer "messages" in the events of the discrete event simulation in this chapter. Weren't those messages simply commands to the agent objects, hidden within SimEvent data? A simulation event is actually a message to an object, triggered to go off at some point in the (simulated) future.

In a real sense, this thin line between structure and behavior is exactly how computer viruses work. A computer virus typically loads into your computer as data. It just so happens that the data that gets loaded in is actually executable code. The virus enters into your computer (through techniques like *buffer overflow*) as data, but structured in such a way that the executable instructions can get executed. That structuring is typically based on some insight about some flaw about your computer—some place

where data can get handled in such a way that some of it can become behavior. Once your computer is executing instructions that the virus writer wrote, all is lost. Your computer's behavior belongs to the virus writer, who snuck in his behavior through some flaw in the computer structure.

These complicated interactions between stuff (structure) and how it works (behavior) are difficult to describe. A program describes them, but only be tracing or executing it. We often want ways of thinking about these interactions without having to read the whole program.

That is where our UML diagrams come in. They give us the ability to oversee the *model* (which is defined both in terms of structure and the behavior of that structure), without getting stuck in implementation complexity. It's pretty hard to trace through the interactions between agents, resources, and event queues in the actual execution of a discrete event simulation. The class diagram makes it so much clearer.

Here is the interesting question to ponder: Where is the program? In languages like Python or Basic, the program is often in one big file, defined through a set of functions, that one can point at. In Java and other object-oriented programs, the program is spread across many objects, many files, where the flow of behavior moves between all these pieces.

The insight that we hope that you come away with, at the end of this book, is that the *actual* program, what really happens, is a mixture of all of that, plus data structures. The definition of what the program does can also be structured by what is in the data, like our special branches in our sound and image trees. The program, thus, is distributed across many computational entities. Programs are distributed across all your representations of structure and behavior.

Program Example #152

Example Java Code: **WolfDeerSimulation.java**

```
import java.io.*;  // For BufferedWriter

public class WolfDeerSimulation {

  /* Linked lists for tracking wolves and deer */
  private AgentNode wolves;
  private AgentNode deer;

  /** Accessors for wolves and deer */
  public AgentNode getWolves(){return wolves;}
  public AgentNode getDeer(){return deer;}

  /* A BufferedWriter for writing to */
  public BufferedWriter output;
```

```
16    /**
       * Constructor to set output to null
18     **/
      public WolfDeerSimulation() {
20      output = null;
      }
22
      /**
24     * Open the input file and set the BufferedWriter to speak to it.
       **/
26    public void openFile(String filename){
       // Try to open the file
28      try {

30        // create a writer
          output = new BufferedWriter(new FileWriter(filename));
32
        } catch (Exception ex) {
34        System.out.println("Trouble opening the file " + filename);
          // If any problem, make it null again
36        output = null;
        }
38
      }
40
      public void run()
42    {
        World w = new World();
44      w.setAutoRepaint(false);

46      // Start the lists
        wolves = new AgentNode();
48      deer = new AgentNode();

50      // create some deer
        int numDeer = 20;
52      for (int i = 0; i < numDeer; i++)
        {
54        deer.add(new AgentNode(new Deer(w,this)));
        }
56
        // create some wolves
58      int numWolves = 5;
        for (int i = 0; i < numWolves; i++)
60      {
          wolves.add(new AgentNode(new HungryWolf(w,this)));
62      }

64      // declare a wolf and deer
        Wolf currentWolf = null;
```

```
66      Deer currentDeer = null;
        AgentNode currentNode = null;
68
        // loop for a set number of timesteps (50 here)
70      for (int t = 0; t < 50; t++)
        {
72        // loop through all the wolves
          currentNode = (AgentNode) wolves.getNext();
74        while (currentNode != null)
          {
76          currentWolf = (Wolf) currentNode.getAgent();
            currentWolf.act();
78          currentNode = (AgentNode) currentNode.getNext();
          }
80
          // loop through all the deer
82        currentNode = (AgentNode) deer.getNext();
          while (currentNode != null)
84        {
            currentDeer = (Deer) currentNode.getAgent();
86          currentDeer.act();
            currentNode = (AgentNode) currentNode.getNext();
88        }

90        // repaint the world to show the movement
          w.repaint();
92
          // Let's figure out where we stand...
94        System.out.println(">>> Timestep: "+t);
          System.out.println("Wolves left: "+wolves.getNext().count());
96        System.out.println("Deer left: "+deer.getNext().count());

98        // If we have an open file, write the counts to it
          if (output != null) {
