

## Double Header

- **Two Lectures**
  - Model Checking
  - Software Model Checking
  - SLAM and BLAST
- “Flying Boxes”
  - It is traditional to describe this stuff (especially SLAM and BLAST) with high-gloss animation. Sorry.
- Some Key Players:
  - Model Checking: Ed Clarke, Ken McMillan, Amir Pnueli
  - SLAM: Tom Ball, Sriram Rajamani
  - BLAST: Ranjit Jhala, Rupak Majumdar, Tom Henzinger

## Overarching Plan

- **Model Checking**
  - Transition Systems (Models)
  - Temporal Properties
  - LTL and CTL
  - (Explicit State) Model Checking
  - Symbolic Model Checking
- **Counterexample Guided Abstraction Refinement**
  - Safety Properties
  - Predicate Abstraction (“c2bp”)
  - Software Model Checking (“bebop”)
  - Counterexample Feasibility (“newton”, “hw 5”)
  - Abstraction Refinement (weakest pre, thrm prvr)

## Spoiler Space

- **This stuff really works!**
  - This is not ESC or PCC or Denotational Semantics
- Symbolic Model Checking is a massive success in the model-checking field
  - I know people who think Ken McMillan walks on water in a “ha-ha-ha only serious” way
- SLAM took the PL world by storm
  - Spawned multiple copycat projects
  - Incorporated into Windows DDK as “static driver verifier”

## Topic:

### (Generic) Model Checking

- There are complete courses in model checking; I will skim.
  - Model Checking by Edmund C. Clarke, Orna Grumberg, and Doron A. Peled, MIT press
  - Symbolic Model Checking by Ken McMillan

## Model Checking

- Model checking is an automated technique
- Model checking verifies transition systems
- Model checking verifies temporal properties
- Model checking can be also used for falsification by generating counter-examples
- **Model Checker:** A program that checks if a (transition) system satisfies a (temporal) property

## Verification vs. Falsification

- An automated verification tool
  - can report that the system is **verified** (with a **proof**)
  - or that the system was **not verified** (with ???)
- When the system was not verified it would be helpful to explain why
  - Model checkers can output an error **counter-example**: a concrete execution scenario that demonstrates the error
- Can view a model checker as a **falsification tool**
  - The main goal is to find bugs
- OK, so what can we verify or falsify?

#7

## Temporal Properties

- **Temporal Property**: A property with temporal operators such as “invariant” or “eventually”
- **Invariant(*p*)**: is true in a state if property *p* is true in **every** state on all execution paths starting at that state
  - The Invariant operator has different names in different temporal logics:
    - G, AG, □ (“goal” or “box” or “forall”)
- **Eventually(*p*)**: is true in a state if property *p* is true at **some** state on every execution path starting from that state
  - F, AF, ◇ (“diamond” or “future” or “exists”)

#8

## An Example Concurrent Program

- A simple **concurrent mutual exclusion program**
- Two processes execute asynchronously
- There is a shared variable **turn**
- Two processes use the shared variable to ensure that they are **not in the critical section at the same time**
- Can be viewed as a “fundamental” program: any bigger concurrent one would include this one

```

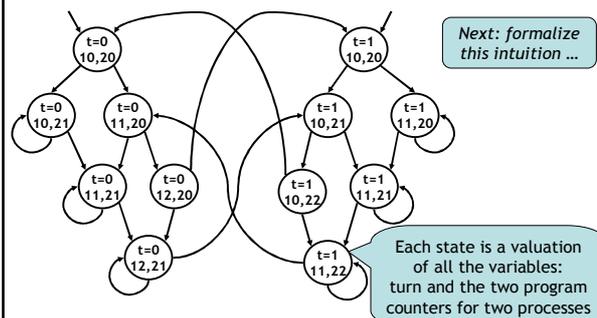

10: while True do
11:   wait(turn = 0);
      // critical section
12:   turn := 1;
13: end while;

|| // concurrently with

20: while True do
21:   wait(turn = 1);
      // critical section
22:   turn := 0;
23: end while
    
```

#9

## Reachable States of the Example Program

#10

## Transition Systems

- In model checking the system being analyzed is represented as a **labeled transition system**

$$T = (S, I, R, L)$$
  - Also called a **Kripke Structure**
  - $S$  = Set of states // standard FSM
  - $I \subseteq S$  = Set of initial states // standard FSM
  - $R \subseteq S \times S$  = Transition relation // standard FSM
  - $L: S \rightarrow \mathcal{P}(AP)$  = Labeling function // this is new!
- **AP**: Set of **atomic propositions** (e.g., “x=5”)
  - Atomic propositions capture basic properties
  - For software, atomic props depend on variable values
  - The labeling function labels each state with the set of propositions true in that state

#11

## Properties of the Program

- Example: “In all the reachable states (configurations) of the system, the two processes are *never in the critical section at the same time*”
  - Equivalently, we can say that
    - $\text{Invariant}(\neg(\text{pc1}=12 \wedge \text{pc2}=22))$
- Also: “*Eventually the first process enters the critical section*”
  - $\text{Eventually}(\text{pc1}=12)$
- “**pc1=12**”, “**pc2=22**” are atomic properties

#12

## Temporal Logics

- There are four basic temporal operators:
  - 1)  $X p$  = Next  $p$ ,  $p$  holds in the next state
  - 2)  $G p$  = Globally  $p$ ,  $p$  holds in every state,  $p$  is an invariant
  - 3)  $F p$  = Future  $p$ ,  $p$  will hold in a future state,  $p$  holds eventually
  - 4)  $p U q$  =  $p$  Until  $q$ , assertion  $p$  will hold until  $q$  holds
- Precise meaning of these temporal operators are defined on execution paths

#13

## Execution Paths

- A **path** in a transition system is an infinite sequence of states  $(s_0, s_1, s_2, \dots)$ , such that  $\forall i \geq 0. (s_i, s_{i+1}) \in R$
- A path  $(s_0, s_1, s_2, \dots)$  is an **execution path** if  $s_0 \in I$
- Given a path  $x = (s_0, s_1, s_2, \dots)$ 
  - $x_i$  denotes the  $i^{\text{th}}$  state  $s_i$
  - $x^i$  denotes the  $i^{\text{th}}$  suffix  $(s_i, s_{i+1}, s_{i+2}, \dots)$
- In some temporal logics one can quantify the paths starting from a state using **path quantifiers**
  - A : for all paths
  - E : there exists a path

#14

## Linear Time Logic (LTL)

- LTL properties are constructed from atomic propositions in AP; logical operators  $\wedge, \vee, \neg$ ; and temporal operators X, G, F, U.
- The semantics of LTL properties is defined on paths:

Given a path  $x$ :

$x \models p$	iff	$L(x_0, p)$	// atomic prop
$x \models X p$	iff	$x^1 \models p$	// next
$x \models F p$	iff	$\exists i \geq 0. x^i \models p$	// future
$x \models G p$	iff	$\forall i \geq 0. x^i \models p$	// globally
$x \models p U q$	iff	$\exists i \geq 0. x^i \models q$ and $\forall j < i. x^j \models p$	// until

#15

## Satisfying Linear Time Logic

- Given a transition system  $T = (S, I, R, L)$  and an LTL property  $p$ , **T satisfies p** if **all paths** starting from **all initial states I** satisfy  $p$
- Examples:
  - **Invariant**( $\neg(\text{pc1}=12 \wedge \text{pc2}=22)$ ):  
 $G(\neg(\text{pc1}=12 \wedge \text{pc2}=22))$
  - **Eventually**( $\text{pc1}=12$ ):  
 $F(\text{pc1}=12)$

#16

## Computation Tree Logic (CTL)

- In CTL temporal properties use **path quantifiers**
  - A : for all paths
  - E : there exists a path
- The semantics of CTL properties is defined on states:

Given a path  $x$

$s \models p$	iff	$L(s, p)$
$s_0 \models EX p$	iff	$\exists$ a path $(s_0, s_1, s_2, \dots). s_1 \models p$
$s_0 \models AX p$	iff	$\forall$ paths $(s_0, s_1, s_2, \dots). s_1 \models p$
$s_0 \models EG p$	iff	$\exists$ a path $(s_0, s_1, s_2, \dots). \forall i \geq 0. s_i \models p$
$s_0 \models AG p$	iff	$\forall$ paths $(s_0, s_1, s_2, \dots). \forall i \geq 0. s_i \models p$

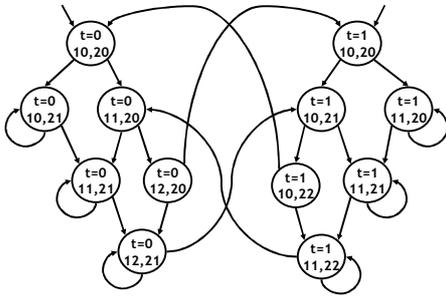

#17

## Linear vs. Branching Time

- LTL is a **linear time logic**
  - When determining if a path satisfies an LTL formula we are only concerned with a **single path**
- CTL is a **branching time logic**
  - When determining if a state satisfies a CTL formula we are concerned with **multiple paths**
  - In CTL the computation is not viewed as a single path but as a **computation tree** which contains all the paths
  - The computation tree is obtained by unrolling the transition relation
- The expressive powers of CTL and LTL are incomparable
  - Basic temporal properties can be expressed in both logics
  - Not in this lecture, sorry! (Take a class on Modal Logics)

#18

## Remember the Example

#19

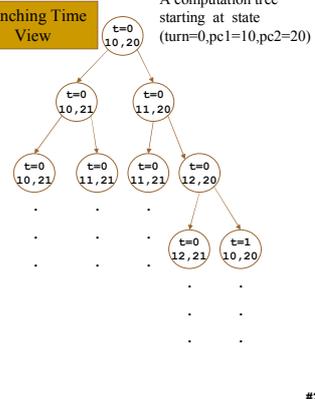

A path starting at state  
(turn=0, pc1=10, pc2=20)

## Linear vs. Branching Time

Linear Time View

Branching Time View

A computation tree starting at state  
(turn=0, pc1=10, pc2=20)

#20

## LTL Satisfiability Examples

○ p does not hold    ● p holds

On this path: F p holds, G p does not hold, p does not hold, X p does not hold, X (X p) holds, X (X (X p)) does not hold

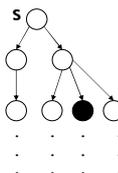

On this path: F p holds, G p holds, p holds, X p holds, X (X p) holds, X (X (X p)) holds

#21

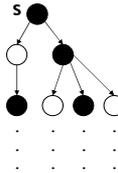

○ p does not hold  
● p holds

## CTL Examples

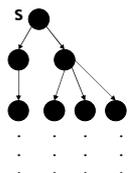

At state s:  
EF p, EX (EX p),  
AF (¬p), ¬p holds

AF p, AG p,  
AG (¬p), EX p,  
EG p, p does not hold

At state s:  
EF p, AF p,  
EX (EX p),  
EX p, EG p, p holds

AG p, AG (¬p),  
AF (¬p) does not hold

At state s:  
EF p, AF p,  
AG p, EG p,  
EX p, AX p, p holds

EG (¬p), EF (¬p),  
does not hold

#22

## Model Checking Complexity

- Given a transition system  $T = (S, I, R, L)$  and a CTL formula  $f$ 
  - One can check if a state of the transition system satisfies the temporal logic formula  $f$  in  $O(|f| \times (|S| + |R|))$  time
- Given a transition system  $T = (S, I, R, L)$  and an LTL formula  $f$ 
  - One can check if the transition system satisfies the temporal logic formula  $f$  in  $O(2^{|f|} \times (|S| + |R|))$  time
- Model checking procedures can generate counter-examples without increasing the complexity of verification (= "for free")

#23

## State Space Explosion

- The complexity of model checking increases linearly with respect to the size of the transition system ( $|S| + |R|$ )
- However, the size of the transition system ( $|S| + |R|$ ) is exponential in the number of variables and number of concurrent processes
- This exponential increase in the state space is called the state space explosion
  - Dealing with it is one of the major challenges in model checking research

#24

## Explicit-State Model Checking

- One can show the complexity results using **depth first search** algorithms
  - The transition system is a directed graph
  - CTL model checking is multiple depth first searches (one for each temporal operator)
  - LTL model checking is one nested depth first search (i.e., two interleaved depth-first-searches)
  - Such algorithms are called **explicit-state model checking** algorithms (details on next slides)

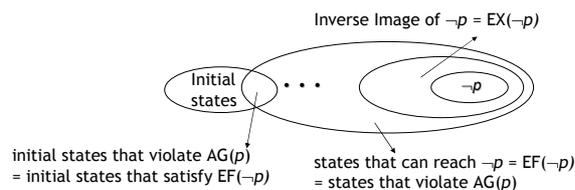

#25

## Temporal Properties $\equiv$ Fixpoints

- States that satisfy **AG(p)** are all the states which are not in **EF( $\neg p$ )** (= the states that can reach  $\neg p$ )
- Compute **EF( $\neg p$ )** as the **fixpoint** of  $\text{Func}: 2^S \rightarrow 2^S$
- Given  $Z \subseteq S$ ,
  - $\text{Func}(Z) = \neg p \cup \text{reach-in-one-step}(Z)$  This is called the inverse image of Z
  - or  $\text{Func}(Z) = \neg p \cup \text{EX}(Z)$
- Actually, **EF( $\neg p$ )** is the **least-fixpoint** of  $\text{Func}$ 
  - smallest set  $Z$  such that  $Z = \text{Func}(Z)$
  - to compute the least fixpoint, start the iteration from  $Z = \emptyset$ , and apply the  $\text{Func}$  until you reach a fixpoint
  - This can be **computed** (unlike most other fixpoints)

#26

## Pictorial Backward Fixpoint

This fixpoint computation can be used for:

- verification of  $EF(\neg p)$
- or falsification of  $AG(p)$

... and a similar forward fixpoint handles the rest

#27

## Symbolic Model Checking

- **Symbolic Model Checking** represent state sets and the transition relation as **Boolean logic formulas**
  - Fixpoint computations **manipulate sets of states** rather than individual states
  - Recall: we needed to compute  $EX(Z)$ , but  $Z \subseteq S$
- Forward and backward fixpoints can be computed by iteratively manipulating these formulas
  - Forward, inverse image: Existential variable elimination
  - Conjunction (intersection), disjunction (union) and negation (set difference), and equivalence check
- Use an **efficient data structure** for manipulation of Boolean logic formulas
  - **Binary Decision Diagrams (BDDs)**

#28

## Binary Decision Diagrams (BDDs)

- **Efficient** representation for **boolean functions** (a set can be viewed as a function)
- Disjunction, conjunction complexity: at most quadratic
- Negation complexity: constant
- Equivalence checking complexity: constant or linear
- Image computation complexity: can be exponential

#29

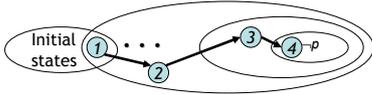

## Symbolic Model Checking Using BDDs

- SMV (Symbolic Model Verifier) was the first CTL model checker to use a BDD representation
- It has been successfully used in verification of
  - hardware specifications, software specifications, protocols, etc.
- SMV verifies finite state systems
  - It supports both synchronous and asynchronous composition
  - It can handle boolean and enumerated variables
  - It can handle bounded integer variables using a binary encoding of the integer variables
    - It is not very efficient in handling integer variables although this can be fixed

#30

## Where's the Beef

- To produce the **explicit counter-example**, use the "onion-ring method"
  - A counter-example is a valid **execution path**
  - For each Image Ring (= set of states), find a state and link it with the concrete transition relation R
  - Since each Ring is "reached in one step from previous ring" (e.g., Ring#3 = EX(Ring#4)) this works
  - Each state z comes with L(z) so you know what is true at each point (= what the values of variables are)

#31

## Topic:

## Software Model Checking via Counter-Example Guided Abstraction Refinement

- There are easily two dozen SLAM/BLAST/MAGIC papers; **I will skim.**

#32

## Key Terms

- CEGAR = Counterexample guided abstraction refinement.** A successful software model-checking approach. Sometimes called "Iterative Abstraction Refinement".
- SLAM = The first CEGAR project/tool.** Developed at MSR.
- Lazy Abstraction = A CEGAR optimization** used in the BLAST tool from Berkeley.
- Other terms: c2bp, bebop, newton, npackets++, MAGIC, flying boxes, etc.

#33

## So ... what is Counterexample Guided Abstraction Refinement?

- Theorem Proving?
- Dataflow Analysis?
- Model Checking?

#34

## Verification by Theorem Proving

```

Example ( ) {
1: do{
    lock();
    old = new;
    q = q->next;
2:   if (q != NULL){
3:     q->data = new;
    unlock();
    new ++;
  }
4: } while(new != old);
5: unlock ();
return;
}
    
```

1. Loop Invariants
2. Logical formula
3. Check Validity

Invariant:  
 $lock \wedge new = old$   
 $\vee$   
 $\neg lock \wedge new \neq old$

#35

## Verification by Theorem Proving

```

Example ( ) {
1: do{
    lock();
    old = new;
    q = q->next;
2:   if (q != NULL){
3:     q->data = new;
    unlock();
    new ++;
  }
4: } while(new != old);
5: unlock ();
return;
}
    
```

1. Loop Invariants
2. Logical formula
3. Check Validity

- Loop Invariants  
 - Multithreaded Programs  
 + Behaviors encoded in logic  
 + Decision Procedures

Precise [ESC, PCC]

#36

## Verification by Program Analysis

```

Example ( ) {
1: do{
    lock();
    old = new;
    q = q->next;
2:   if (q != NULL){
3:     q->data = new;
    unlock();
    new ++;
    }
4: } while(new != old);
5: unlock ();
return;
}
    
```

1. Dataflow Facts
2. Constraint System
3. Solve constraints

- Imprecision due to fixed facts  
 + Abstraction  
 + Type/Flow Analyses  
 Scalable [CQUAL, ESP, MC]

#37

## Verification by Model Checking

```

Example ( ) {
1: do{
    lock();
    old = new;
    q = q->next;
2:   if (q != NULL){
3:     q->data = new;
    unlock();
    new ++;
    }
4: } while(new != old);
5: unlock ();
return;
}
    
```

1. (Finite State) Program
2. State Transition Graph
3. Reachability

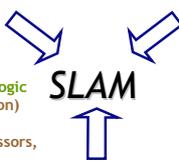

- Pgm → Finite state model  
 - State explosion  
 + State Exploration  
 + Counterexamples  
 Precise [SPIN, SMV, Bandera, JPF]

#38

## Combining Strengths

### Theorem Proving

- Need loop invariants  
 (will find automatically)  
 + Behaviors encoded in logic  
 (used to refine abstraction)  
 + Theorem provers  
 (used to compute successors,  
 refine abstraction)

### Program Analysis

- Imprecise  
 (will be precise)  
 + Abstraction  
 (will shrink the state space  
 we must explore)

### Model Checking

- Finite-state model, state explosion  
 (will find small good model)  
 + State Space Exploration  
 (used to get a path sensitive analysis)  
 + Counterexamples  
 (used to find relevant facts, refine abstraction)

#39

## Homework

- Project Status Update
- Project Due Tue Apr 25
  - You have -14 days to complete it.
  - Need help? Stop by my office or send email.

#40
