Abstract Interpretation

(Galois, Collections, Widening)

One Slide Summary

- In abstract interpretation, the abstraction function
 β and concretization function γ form a Galois
 connection: they are almost inverses.
- To abstract the state σ at each program point we use a collecting semantics (the abstract domain holds sets of states). This shows the link between abstract interpretation and model checking.
- This will result in recursively-defined equations. We use the fixed point theorem to solve them. This shows the link between abstract interpretation and dataflow analysis.
- Widening operators help accelerate convergence.

Abstract Interpretation

- We have an abstract domain A
 - e.g., A = { positive, negative, zero }
 - An abstraction function $\beta:\mathbb{Z}\to A$
 - ${\scriptstyle \bullet} \ensuremath{\mathbb Z}$ is our concrete domain
 - A concretization function $\gamma : A \to \mathcal{P}(\mathbb{Z})$
- Positive + Positive = ???
- Positive + Negative = ???
- Positive / Zero = ???

We don't want security to get suspicious ...

Review

- We introduced abstract interpretation
- An abstraction mapping from concrete to abstract values
 - Has a concretization mapping which forms a Galois connection
- We'll look a bit more at Galois connections
- We'll lift AI from expressions to programs
- ... and we'll discuss the mythic "widening"

Why Galois Connections?

- We have an abstract domain A
 - An abstraction function $\beta:\mathbb{Z}\to A$
 - Induces $\alpha : \mathcal{P}(\mathbb{Z}) \to A$ and $\gamma : A \to \mathcal{P}(\mathbb{Z})$
- We argued that for correctness

 $\gamma(a_1 \text{ op } a_2) \supseteq \gamma(a_1) \text{ op } \gamma(a_2)$

- We wish for the set on the left to be as small as possible
- To reduce the loss of information through abstraction
- For each set $S \subseteq C$, define $\alpha(S)$ as follows:
 - Pick smallest S' that includes S and is in the image of γ
 - Define $\alpha(S) = \gamma^{-1}(S')$
 - Then we define: $a_1 op a_2 = \alpha(\gamma(a_1) op \gamma(a_2))$
- Then α and γ form a Galois connection

Galois Connections

- A <u>Galois connection</u> between complete lattices A and P(C) is a pair of functions α and γ such that:
 - γ and α are monotonic
 - (with the \subseteq ordering on $\mathcal{P}(C)$)
 - α (γ (a)) = a for all a \in A
 - γ (α(S)) <u>⊃</u> S

γα

for all $S \in \mathcal{P}(C)$

1,2

More on Galois Connections

IS FREEDOM OF SPEECH AN ABSOLUTE RIGHT? anything which hurts other people's convictions, particularly religious convictions, must be avoided. **Freedom of** expression should be exercised in a spirit of responsibility. I must condemn any overt provocatio "I may not agree with that could what you say but I will dangerously defend to the death fuel passion your right to say it."

- All Galois connections are monotonic
- In a Galois connection one function uniquely and absolutely determines the other

Abstract Interpretation for Imperative Programs

- So far we abstracted the value of expressions
- Now we want to abstract the state at each point in the program
- First we define the concrete semantics that we are abstracting
 - We'll use a collecting semantics

Collecting Semantics

- Recall
 - A state $\sigma \in \Sigma$. Any state σ has type Var $\to \mathbb{Z}$
 - States vary from program point to program point
- We introduce a set of program points: labels
- We want to answer questions like:
 - Is x always positive at label i?
 - Is x always greater or equal to y at label j?
- To answer these questions we'll construct
 - $C \in Contexts$. C has type Labels $\rightarrow \mathcal{P}(\Sigma)$
 - For each label i, C(i) = all possible states at label i
 - This is called the <u>collecting semantics</u> of the program
 - This is basically what SLAM (and BLAST, ESP, ...) approximate (using BDDs to store $\mathcal{P}(\Sigma)$ efficiently)

- We first define relations between the collecting semantics at different labels
 - We do it for unstructured CFGs (cf. HW6!)
 - Can do it for IMP with careful notion of program points
- Define a label on each edge in the CFG
- For assignment

$$\begin{array}{c} \downarrow i \\ \hline x := e \\ \downarrow j \end{array} \quad C_j = \{ \sigma[x := n] \mid \sigma \in C_i \land e \Downarrow \sigma = n \} \end{array}$$

• For conditionals

• Assumes b has no side effects (as in IMP or HW6)

• For a join

Verify that these relations are monotonic
 If we increase a C_x all other C_y can only increase

Assume x ≥ 0 initially (explain this?)

Why Does This Work?

 We just made a system of recursive equations that are defined largely in terms of themselves

- e.g., $C_2 = F(C_4)$, $C_4 = G(C_3)$, $C_3 = H(C_2)$

 Why do we have any reason to believe that this will get us what we want?

The Collecting Semantics

- We have an equation with the unknown C
 - The equation is defined by a monotonic and continuous function on domain Labels $\rightarrow \mathcal{P}(\Sigma)$
- We can use the least fixed-point theorem
 - Start with $C^{0}(L) = \emptyset$ (aka $C^{0} = \lambda L.\emptyset$)
 - Apply the relations between C_i and C_j to get C¹_i from C⁰_j
 - Stop when all $C^k = C^{k-1}$
 - Problem: we'll go on forever for most programs
 - But we know the fixed point exists

$$C_{1} = \{ \sigma \mid \sigma(\mathbf{x}) \ge 0 \}$$

$$C_{2} = \{ \sigma[\mathbf{y}:=1] \mid \sigma \in C_{1} \}$$

$$\cup \{ \sigma[\mathbf{x}:=\sigma(\mathbf{x})-1] \mid \sigma \in C_{4} \}$$

$$C_{3} = C_{2} \cap \{ \sigma \mid \sigma(\mathbf{x}) \neq 0 \}$$

$$C_{5} = C_{2} \cap \{ \sigma \mid \sigma(\mathbf{x}) = 0 \}$$

$$C_{4} = \{ \sigma[\mathbf{y}:=\sigma(\mathbf{y})^{*}\sigma(\mathbf{x}) \mid \sigma \in C_{3} \}$$

$$\#^{2} 4$$

• (assume $x \ge 0$ initially)

 $C_{1} = \{ \sigma \mid \sigma(\mathbf{x}) \ge 0 \}$ $C_{2} = \{ \sigma[\mathbf{y}:=1] \mid \sigma \in C_{1} \}$ $\cup \{ \sigma[\mathbf{x}:=\sigma(\mathbf{x})-1] \mid \sigma \in C_{4} \}$ $C_{3} = C_{2} \cap \{ \sigma \mid \sigma(\mathbf{x}) \neq 0 \}$ $C_{5} = C_{2} \cap \{ \sigma \mid \sigma(\mathbf{x}) = 0 \}$ $C_{4} = \{ \sigma[\mathbf{y}:=\sigma(\mathbf{y})^{*}\sigma(\mathbf{x}) \mid \sigma \in C_{3} \}$

• (assume $x \ge 0$ initially)

 $C_{1} = \{ \sigma \mid \sigma(\mathbf{x}) \ge 0 \}$ $C_{2} = \{ \sigma[\mathbf{y}:=1] \mid \sigma \in C_{1} \}$ $\cup \{ \sigma[\mathbf{x}:=\sigma(\mathbf{x})-1] \mid \sigma \in C_{4} \}$ $C_{3} = C_{2} \cap \{ \sigma \mid \sigma(\mathbf{x}) \neq 0 \}$ $C_{5} = C_{2} \cap \{ \sigma \mid \sigma(\mathbf{x}) = 0 \}$ $C_{4} = \{ \sigma[\mathbf{y}:=\sigma(\mathbf{y})^{*}\sigma(\mathbf{x}) \mid \sigma \in C_{3} \}$

• (assume $x \ge 0$ initially)

 $C_2 = \{ \sigma[y:=1] \mid \sigma \in C_1 \}$ $\cup \{\sigma[\mathbf{x}:=\sigma(\mathbf{x})-1] \mid \sigma \in C_{\mathtt{A}}\}$ $C_3 = C_2 \cap \{\sigma \mid \sigma(\mathbf{x}) \neq 0\}$ $C_5 = C_2 \cap \{\sigma \mid \sigma(x) = 0\}$ $C_4 = \{\sigma[y:=\sigma(y)^*\sigma(x) \mid \sigma \in C_3\}$

Spanish Novels

• This 1605 Spanish novel, *El ingenioso hidalgo* de la Mancha, is considered foundational to Western literature and is the second most-translated book in the world. In it, a noble believes he is a knight-errant and travels with a witty farmer, along the way making social commentary about individuals and society.

Sanskrit Epics & Memory Test

 This Sanskrit epic is one of the two great canon stories of India, and is attributed to the Hindu sage Valmiki. It covers dharma and human values while explaining the protagonist's attempt to recover his wife, Sita, who has been taken by the demons of Lanka. It is heavy on allegory and philosophy. Archery, including an epic use of the brahmastra, is often involved.

Computer Science

 This American Turing-award winner is known for work on the B and C programming languages, the Unix and Plan 9 operating systems, regular expressions in text editors, UTF-8, and chess endgames. Almost all programs that use regular expressions today use his notation for them.

Abstract Interpretation

- Pick a complete lattice A (abstractions for $\mathcal{P}(\Sigma)$)
 - Along with a monotonic abstraction $\alpha : \mathcal{P}(\Sigma) \to A$
 - Alternatively, pick $\beta : \Sigma \to A$
 - This uniquely defines its Galois connection γ
- Take the relations between C_i and move them to the abstract domain:

 $a:Label \to A$

• Assignment

$$\begin{array}{l} \text{Concrete: } \mathsf{C}_{\mathsf{j}} = \{ \sigma[\mathsf{x} := \mathsf{n}] \mid \sigma \in \mathsf{C}_{\mathsf{i}} \land \mathsf{e} \Downarrow \sigma = \mathsf{n} \} \\ \text{Abstract: } \mathsf{a}_{\mathsf{j}} = \alpha \; \{ \sigma[\mathsf{x} := \mathsf{n}] \mid \sigma \in \gamma(\mathsf{a}_{\mathsf{i}}) \land \mathsf{e} \Downarrow \sigma = \mathsf{n} \} \end{array}$$

Abstract Interpretation

Conditional

Concrete: $C_j = \{ \sigma \mid \sigma \in C_i \land b \bigcup \sigma = false \}$ and $C_k = \{ \sigma \mid \sigma \in C_i \land b \bigcup \sigma = true \}$ Abstract: $a_j = \alpha \{ \sigma \mid \sigma \in \gamma(a_i) \land b \bigcup \sigma = false \}$ and $a_k = \alpha \{ \sigma \mid \sigma \in \gamma(a_i) \land b \bigcup \sigma = true \}$

Join

Least Fixed Points In The Abstract Domain

- We have a recursive equation with unknown "a"
 - Defined by a monotonic and continuous function on the domain Labels \rightarrow A
- We can use the least fixed-point theorem:
 - Start with $a^0 = \lambda L. \bot$ (aka: $a^0(L) = \bot$)
 - Apply the monotonic function to compute $a^{k\!+\!1}$ from a^k
 - Stop when $a^{k+1} = a^k$
- Exactly the same computation as for the collecting semantics
 - What is new?
 - "There is nothing new under the sun but there are lots of old things we don't know." - Ambrose Bierce

Least Fixed Points In The Abstract Domain

- We have a hope of termination!
- Classic setup: A has only <u>uninteresting</u> chains (finite number of elements in each chain)
 - A has finite height h (= "<u>finite-height lattice</u>")
- The computation takes $O(h \times |Labels|^2)$ steps
 - At each step "a" makes progress on at least one label
 - We can only make progress h times
 - And each time we must compute |Labels| elements
- This is a quadratic analysis: good news
 - This is exactly the same as Kildall's 1973 analysis of dataflow's polynomial termination given a finite-height lattice and monotonic transfer functions.

Abstract Interpretation: Example

• Consider the following program, x>0

Abstract Domain for Sign Analysis

Invent the complete sign lattice

 $S = \{ \perp, -, 0, +, \top \}$

Construct the complete lattice

 $\mathsf{A} = \{\mathsf{x}, \, \mathsf{y}\} \to \mathsf{S}$

- With the usual point-wise ordering
- Abstract state gives the sign for x and y
- We start with $a^0 = \lambda L.\lambda v \in \{x,y\}. \perp$

Let's Do It!

Let's Do It!

Notes, Weaknesses, Solutions

• We abstracted the state of each variable independently

 $\mathsf{A} = \{\mathsf{x}, \mathsf{y}\} \rightarrow \{\bot, \text{ -, } \mathsf{0}, \text{ +, } \top\}$

- We lost relationships between variables
 - e.g., at a point x and y may always have the same sign
 - In the previous abstraction we get $\{x := \top, y := \top\}$ at label 2 (when in fact y is always positive!)
- We can also abstract the state as a whole $A = \mathcal{P}(\{\perp, -, 0, +, \top\} \times \{\perp, -, 0, +, \top\})$

Other Abstract Domains

- Range analysis
 - Lattice of ranges: R ={ \perp , [n..m], (- ∞ , m], [n, + ∞), \top }
 - It is a complete lattice
 - [n..m] ⊔ [n'..m'] = [min(n, n')..max(m,m')]
 - [n..m] □ [n'..m'] = [max(n, n')..min(m, m')]
 - With appropriate care in dealing with ∞
 - $\beta : \mathbb{Z} \to R$ such that $\beta(n) = [n..n]$
 - $\alpha : \mathcal{P}(\mathbb{Z}) \to R$ such that $\alpha(S) = lub \{\beta(n) \mid n \in S\} = [min(S)..max(S)]$
 - $\gamma : \mathbb{R} \to \mathcal{P}(\mathbb{Z})$ such that $\gamma(r) = \{ n \mid n \in r \}$
- This lattice has infinite-height chains
 - So the abstract interpretation might not terminate!

Example of Non-Termination

• Consider this (common) program fragment

Example of Non-Termination

- Consider the sequence of abstract states at point 2
 - [1..1], [1..2], [1..3], ...
 - The analysis never terminates
 - Or terminates very late if the loop bound is known statically

The Cullens and the Hales sat at the same table as always, not eating, talking only among them- selves. None of them, especially Edward, glanced my way				
anymore.	One person cannot do nothing			
Example:	more than other people who are also doing nothing.			
None of them bought an apple, especially Edward.				

Example of Non-Termination

- Consider the sequence of abstract states at point 2
 - [1..1], [1..2], [1..3], ...
 - The analysis never terminates
 - Or terminates very late if the loop bound is known statically
- It is time to approximate even more: widening
- We redefine the join (lub) operator of the lattice to ensure that from [1..1] upon union with [2..2] the result is $[1..+\infty)$ and not [1..2]
- Now the sequence of states is

- [1..1], [1, + ∞), [1, + ∞) Done (no more infinite chains)

Formal Definition of Widening (Cousot 16.399 "Abstract Interpretation", 2005)

- A widening \bigtriangledown : (P × P) \rightarrow P on a poset $\langle P, \sqsubseteq \rangle$ satisfies:
 - $\neg \forall x, y \in \mathsf{P} . \quad x \sqsubseteq (x \bigtriangledown y) \land y \sqsubseteq (x \bigtriangledown y)$
 - For all increasing chains $x^0 \sqsubseteq x^1 \sqsubseteq ...$ the increasing chain $y^0 = {}^{def} x^0, ..., y^{n+1} = {}^{def} y^n \bigtriangledown x^{n+1}, ...$ is <u>not</u> strictly increasing.
- Two different main uses:
 - Approximate missing lubs. (Not for us.)
 - Convergence acceleration. (This is the real use.)
 - A widening operator can be used to effectively compute an upper approximation of the least fixpoint of $F \in L \bigtriangledown L$ starting from below when L is computer-representable but does not satisfy the ascending chain condition.

Formal Widening Example [1,1] ∇ $[1,2] = [1,+\infty)$

 Range Analysis on z: 		Original x ⁱ	Widened y ⁱ
L0:	z := 1 ;	x ^{L0} ₀ = ⊥	$y_{0}^{L0} = \bot$
L1:	while z<99 do	$X^{L_{0}} = [1, 1]$	$y_{0}^{L_{0}} = [1, 1]$
L2:	z := z+1	$x_{0}^{L2} = [1,1]$	$y_{0}^{L2} = [1,1]$
L3:	done /* z ≥ 99 */	$x_{0}^{L_{0}} = [2,2]$	$y_{0}^{L_{0}} = [2,2]$
L4:		$x^{L2}_{1} = [1,2]$	$y_{1}^{L2} = [1, +\infty)$
x ^{Li} _j = ^{def} the jth iterative attempt to compute an abstract value for		$x^{L_{1}} = [2, +\infty)$	$y_{1}^{L_{1}} = [2, +\infty)$
		$X^{L4}_{0} = [99, +\infty)$	$y_{0}^{L4} = [99, +\infty)$
Recall lub $S = [min(S)max(S)]$		stable (fewer than 99 iterations!)	
Jub /12 .	$+\infty$) [1 + ∞) = {[1 + ∞)]	•	

Other Abstract Domains

- Linear relationships between variables
 - A convex <u>polyhedron</u> is a subset of \mathbb{Z}^k whose elements satisfy a number of inequalities:

 $a_1x_1 + a_2x_2 + ... + a_kx_k \ge c_i$

- This is a complete lattice; linear programming methods compute lubs
- Linear relationships with at most two variables
 - Convex polyhedra but with ≤ 2 variables per constraint
 - Octagons (x \pm y \geq c) have efficient algorithms
- Modulus constraints (e.g. even and odd)

Abstract Chatter

- AI, Dataflow and Software Model Checking
 - The big three (aside from flow-insensitive type systems) for program analyses
- Are in fact quite related:
 - David Schmidt. *Data flow analysis is model checking of abstract interpretation*. POPL '98.
- AI is usually flow-sensitive (per-label answer)
- AI can be path-sensitive (if your abstract domain includes V, for example), which is just where model checking uses BDD's
- Metal, SLAM, ESP, ... can all be viewed as AI

Abstract Interpretation Conclusions

- Al is a very powerful technique that underlies a large number of program analyses
 - Including Dataflow Analysis and Model Checking
- AI can also be applied to functional and logic programming languages
- There are a few success stories
 - Strictness analysis for lazy functional languages
 - PolySpace for linear constraints
- In most other cases however AI is still slow
- When the lattices have infinite height and widening heuristics are used the result becomes unpredictable
