Announcements

- HW₃ is due Nov 27 (next Wednesday)
- Work on projects!! (presentation after three weeks)

21.1 Bandit problem in stochastic shortest path (continue on the last lecture)**21.1.1 FTRL in the bandit setting**

In every round,

$$x_t = \arg \min_{x \in K} \sum_{s=1}^{t-1} f_s \cdot x + \lambda R(x) \quad (21.1)$$

From the last lecture, we can use estimated loss function. Therefore,

$$x_t = \arg \min_{x \in K} \sum_{s=1}^{t-1} \tilde{f}_s \cdot x + \lambda R(x) \quad (21.2)$$

The regret bound becomes,

$$\begin{aligned} \text{Regret}_T &\leq \sum_{t=1}^T \lambda D_R(x_t, x_t + 1) + \lambda R(x^*) \\ &\leq \sum_{t=1}^T \frac{\|\tilde{f}_t\|_{\star}^2}{\lambda} + \lambda R(x^*) \\ &\leq \frac{T \cdot G}{\lambda} + \lambda D \\ &\leq 2\sqrt{T \cdot G \cdot D} \end{aligned} \quad (21.3)$$

Problem As x_t approaches to the boundary, $\|\tilde{f}_t\|_{\star}^2$ grows very large. So above inequality breaks.

Solution: Use regularization with Self Concordance Function

21.1.2 Self Concordance Function

Classical Newton's method Let our objective function be $g(x)$. we want to minimize

$$\min_{x \in D} g(x) \quad (21.4)$$

By adding self-concordance regularization term R ,

$$\min_{x \in D} g(x) + \lambda R(x) \quad (21.5)$$

The Newton's update rule becomes

$$x_{t+1} \leftarrow x_t + (\nabla_{x_t}^2 R)^{-1} \nabla \hat{g}(x_t) \quad (21.6)$$

Therefore, x_{t+1} is in the ellipsoid centered on x_t .

$$x_{t+1} \in (\nabla_{x_t}^2 R)\text{-ellipsoid}$$

Back to Bandit Optimization Previously, our update rule was

$$x_t = \arg \min_{x \in K} \sum_{s=1}^{t-1} \tilde{f}_s \cdot x + \lambda R(x) \quad (21.7)$$

We approximate f_t as eigenpoles of $(\nabla_{x_t}^2 R)$ -ellipsoid.

$$\tilde{f}_t \approx \lambda_i^{1/2} e_i \quad (21.8)$$

where λ_j and e_j are eigenvalues and unit eigenvalues of $\nabla_{x_t}^2 R$

Figure 1: eigenpols approximation

Then, the new regret bound becomes

$$\begin{aligned} \text{Regret}_T &\leq \sum_{t=1}^T \lambda D_R(x_t, x_{t+1}) + \lambda R(x^*) \\ &\leq \sum_{t=1}^T \frac{\tilde{f}_t^T (\nabla_{x_t}^{-2} R) \tilde{f}_t}{\lambda} + \lambda R(x^*) \\ &\leq \frac{nG \sqrt{\sigma_{i_t}} \sigma_{i_t}^{-1} \sqrt{\sigma_{i_t}}}{\lambda} + \lambda D \theta \log T \\ &\leq 2\sqrt{n \cdot G \cdot D \cdot \theta \cdot T \log T} \end{aligned} \quad (21.9)$$

However, these results are "in expectation" only, and only work against "oblivious adversaries". The general problem is still hard.

21.2 Blackwell Approachability

In standard 2-player 0-sum game, the game matrix M satisfies

- $M \in [0, 1]^{n \times m}$,
- $M_{ij} \in \mathbb{R}^1$ is the payoff for P_1 , when P_1 and P_2 play i and j respectively.

The minimax theorem is

$$\min_p \max_q p^T M q = \max_q \min_p p^T M q \quad (21.10)$$

or equivalently, (strong duality)

$$\begin{aligned} \forall p \exists q : p^T M q &\geq c \\ \exists q \forall p : p^T M q &\geq c \end{aligned} \quad (21.11)$$

Generation Now, we want to generalize this to the case when $M_{ij} \in \mathbb{R}^d$.

Let $r(i, j)$ be the payoff vector for P_1 ,

$$r : \Delta_n \times \Delta_m \rightarrow \mathbb{R}^d$$

This is bilinear!

1. $r(\alpha p_1 + (1 - \alpha)p_2, q) = \alpha r(p_1, q) + (1 - \alpha)r(p_2, q)$
2. $r(p, \alpha q_1 + (1 - \alpha)q_2) = \alpha r(p, q_1) + (1 - \alpha)r(p, q_2)$

In this generalized version, we can define the minimax theorem by

$$\begin{aligned} \forall p \exists q : r(p, q) &\in S \\ \exists q \forall p : r(p, q) &\in S \end{aligned} \quad (21.12)$$

S is a certain convex set applying some constraints. In general, this condition is not satisfied.

Example: A bad case

$$\begin{aligned} r(p, q) &= (p, q) \\ S &= \{(x, y) : x = y\} \end{aligned}$$

$\forall p$, there exists $q = p$ such that $r(p, q) \in S$.
However, there is no q satisfying $\forall p : r(p, q) \in S$

Figure 2: A bad case

21.2.1 Blackwell Approachability Theorem

If r, S, p, q satisfies

$$\forall p, \exists q : r(p, q) \in S \quad (21.13)$$

Then, \exists an adaptive strategy

$$q_t \leftarrow f(p_1, p_2, \dots, p_t) \quad (21.14)$$

such that

$$\frac{1}{T} \sum r(p_t, q_t) \rightarrow S \quad (21.15)$$

or equivalently,

$$\text{dist}\left(\frac{1}{T} \sum r(p_t, q_t), S\right) \rightarrow 0 \quad (21.16)$$

Example In above bad case example, one possible strategy for q is to choose previous p .

$$q_t \leftarrow p_{t-1} \quad (21.17)$$

This strategy satisfies Blackwell Approachability theorem,

$$\text{dist}\left(\frac{1}{T} \sum_{t=1}^T p_t, \frac{1}{T} \sum_{t=0}^{T-1} p_t\right) \rightarrow S \quad (21.18)$$

where $p_0 = q_1$. (initial choice of q)

21.2.2 Halfspace condition

\forall halfspaces $H \supset S, \exists q \forall p$

$$r(p, q) \in H \quad (21.19)$$

Lemma: The followings are equivalent

1. The halfspace condition
2. \forall halfspaces $H \supset S, \forall p, \exists q: r(p, q) \in H$
3. $\forall p, \exists q: r(p, q) \in S$

Proof:

1. 1 and 2 are equivalent
Project $r(p, q)$ into the normal of H , and apply minimax theorem.

2. $3 \Rightarrow 2$
Assume $\exists H, \exists p_{bad}, \forall q$

$$r(p_{bad}, q) \notin H$$

which implies $r(p_{bad}, q) \notin S$ (contradiction)

3. $1 \Rightarrow 3$
If $\exists p_{bad}, \forall q: r(p_{bad}, q) \notin S$
 $\Rightarrow \exists$ hyperplane separating S and $\{r(p_{bad}, q) : q \in \Delta_m\}$, but this hyperplane violates 1. (contradiction)

Figure 3: Separating Hyperplane
