Two methods for getting short dense vectors

- Neural Language Model (word2vec)

- Singular Value Decomposition (SVD)

Two methods for getting short dense vectors

- Neural Language Model (word2vec)

- Singular Value Decomposition (SVD)

Sparse versus dense vectors

- Why dense vectors?
  - Short vectors may be easier to use as features in machine learning (less weights to tune)
  - Dense vectors may generalize better than storing explicit counts
  - They may do better at capturing synonymy:
    - *car* and *automobile* are synonyms; but are represented as distinct dimensions; this fails to capture similarity between a word with *car* as a neighbor and a word with *automobile* as a neighbor

Rank of a Matrix

- What is the rank of a matrix A?

Rank of a Matrix

- What is the rank of a matrix A?
- Number of linearly independent columns or rows of A

$$\mathbf{A} = \begin{bmatrix} 1 & 2 & 1 \\ -2 & -3 & 1 \\ 3 & 5 & 0 \end{bmatrix}$$

Rank of a Matrix

- What is the rank of a matrix A?
- Number of linearly independent columns or rows of A

$$\mathbf{A} = \begin{bmatrix} 1 & 2 & 1 \\ -2 & -3 & 1 \\ 3 & 5 & 0 \end{bmatrix}$$

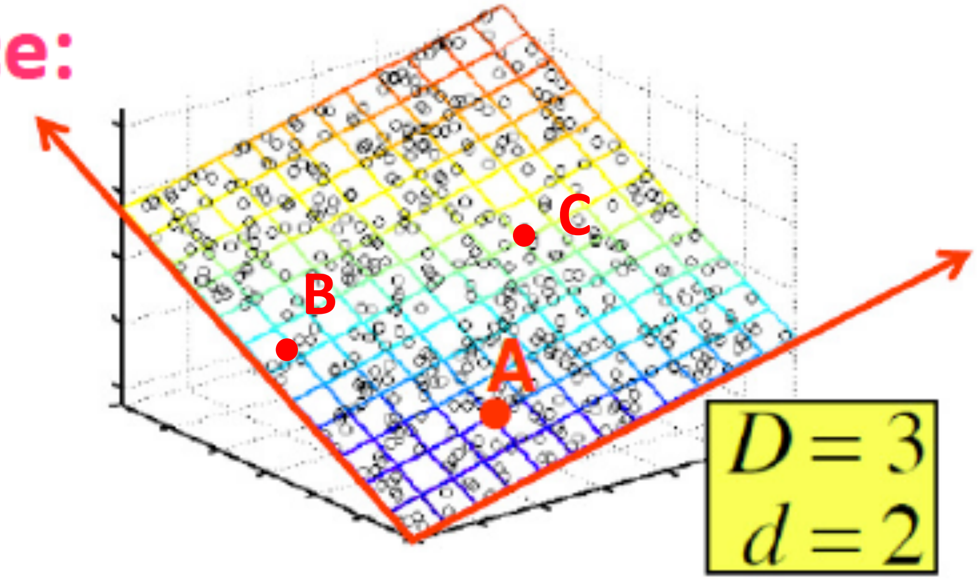
- Rank is 2
- We can rewrite A as two “basis” vectors: [1 2 1] [-2 -3 1]

Rank as “Dimensionality”

Cloud of points 3D space:

- Think of point positions as a matrix:

1 row per point:
$$\begin{array}{ccc|c} 1 & 2 & 1 & A \\ -2 & -3 & 1 & B \\ 3 & 5 & 0 & C \end{array}$$

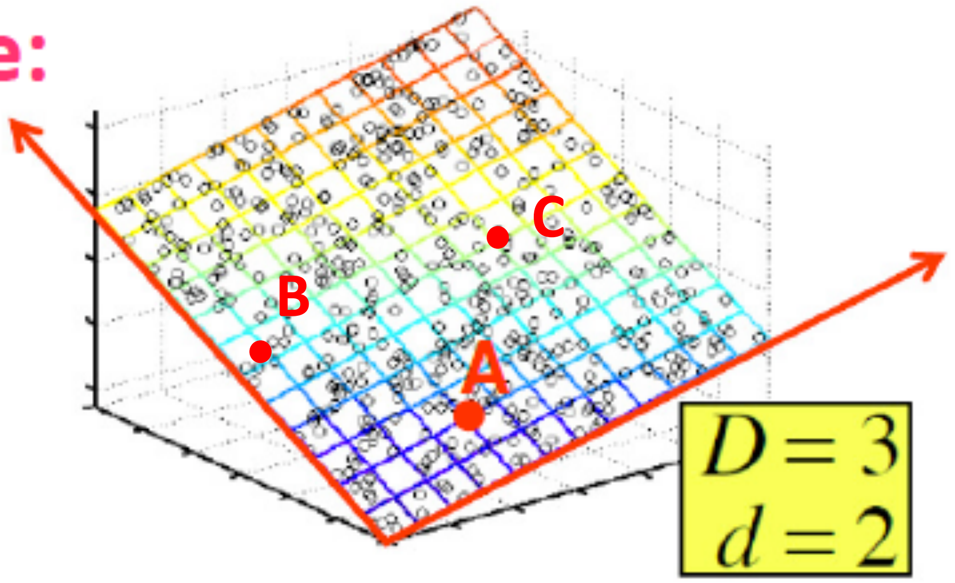


Rank as "Dimensionality"

Cloud of points 3D space:

- Think of point positions as a matrix:

1 row per point: $\begin{array}{c} \\ \\ \\ \end{array}\left[\begin{array}{ccc} 1 & 2 & 1 \\ -2 & -3 & 1 \\ 3 & 5 & 0 \end{array}\right]\begin{array}{c} A \\ B \\ C \end{array}$

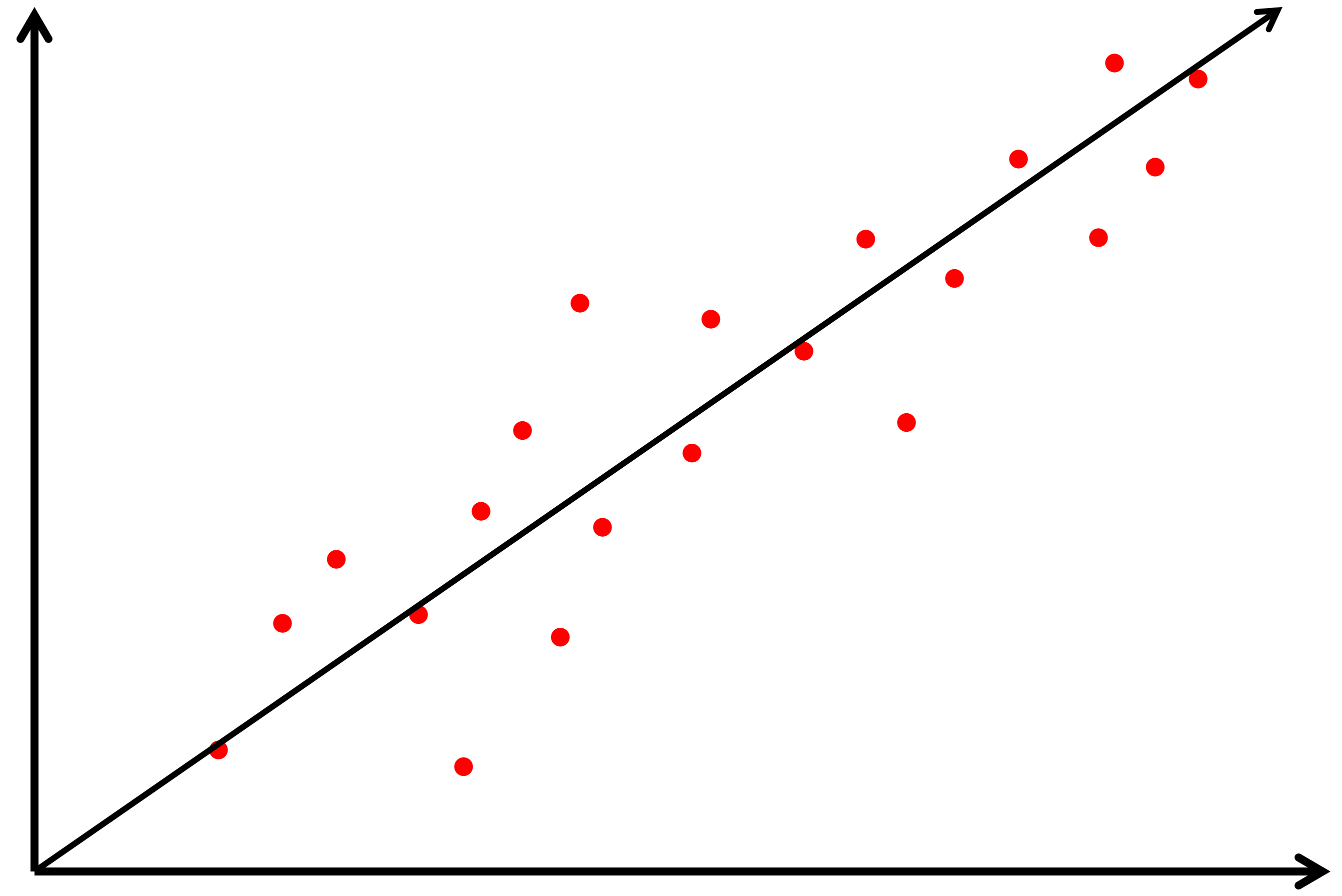


- Rewrite the coordinates in a more efficient way!
  - Old basis vectors: [1 0 0], [0 1 0], [0 0 1]
  - New basis vectors: [1 2 1], [-2 -3 1]

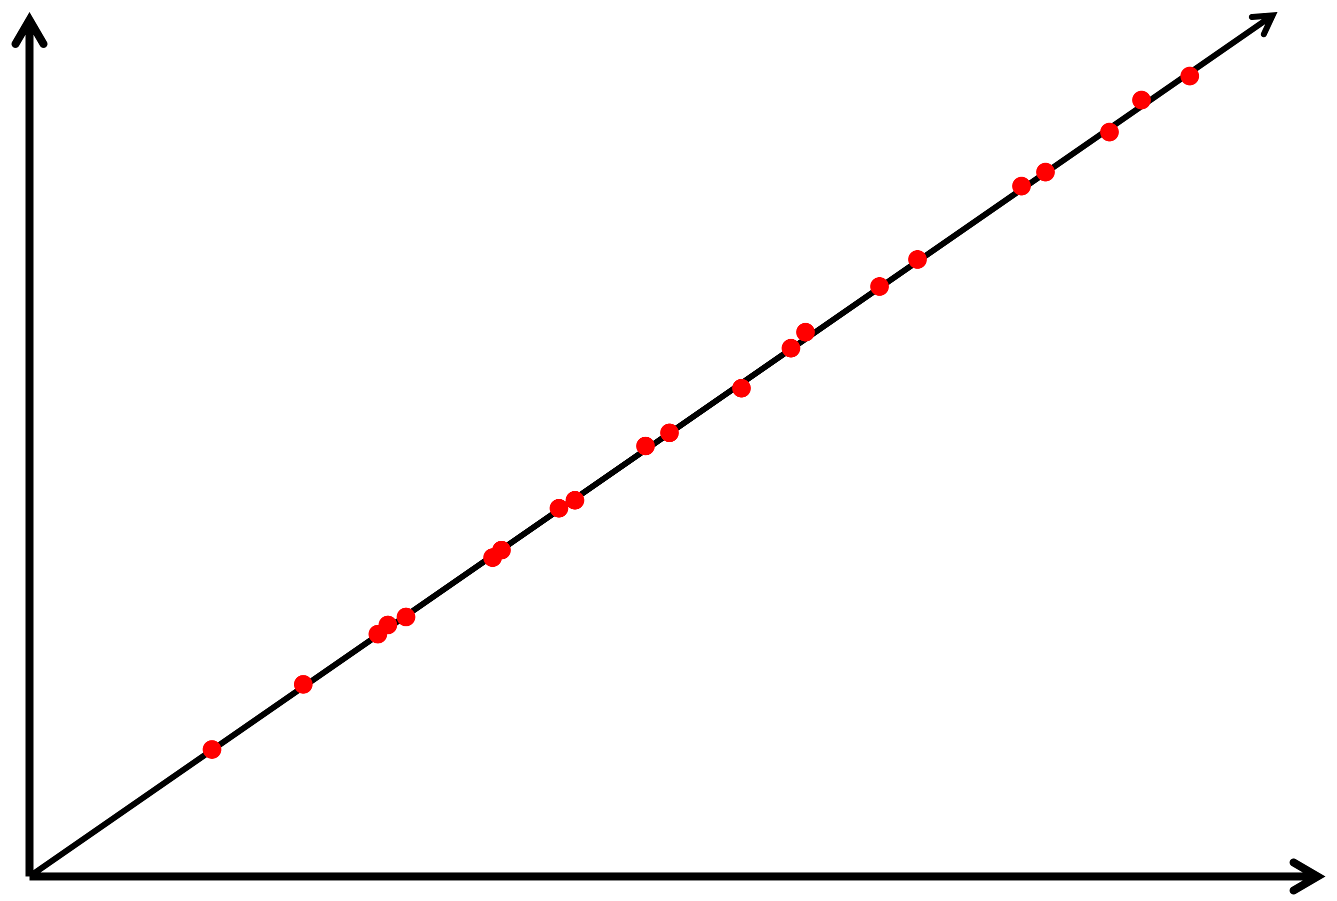
Intuition of Dimensionality Reduction

- Approximate an N-dimensional dataset using fewer dimensions
- By first rotating the axes into a new space
- In which the highest order dimension captures the most variance in the original dataset
- And the next dimension captures the next most variance, etc.

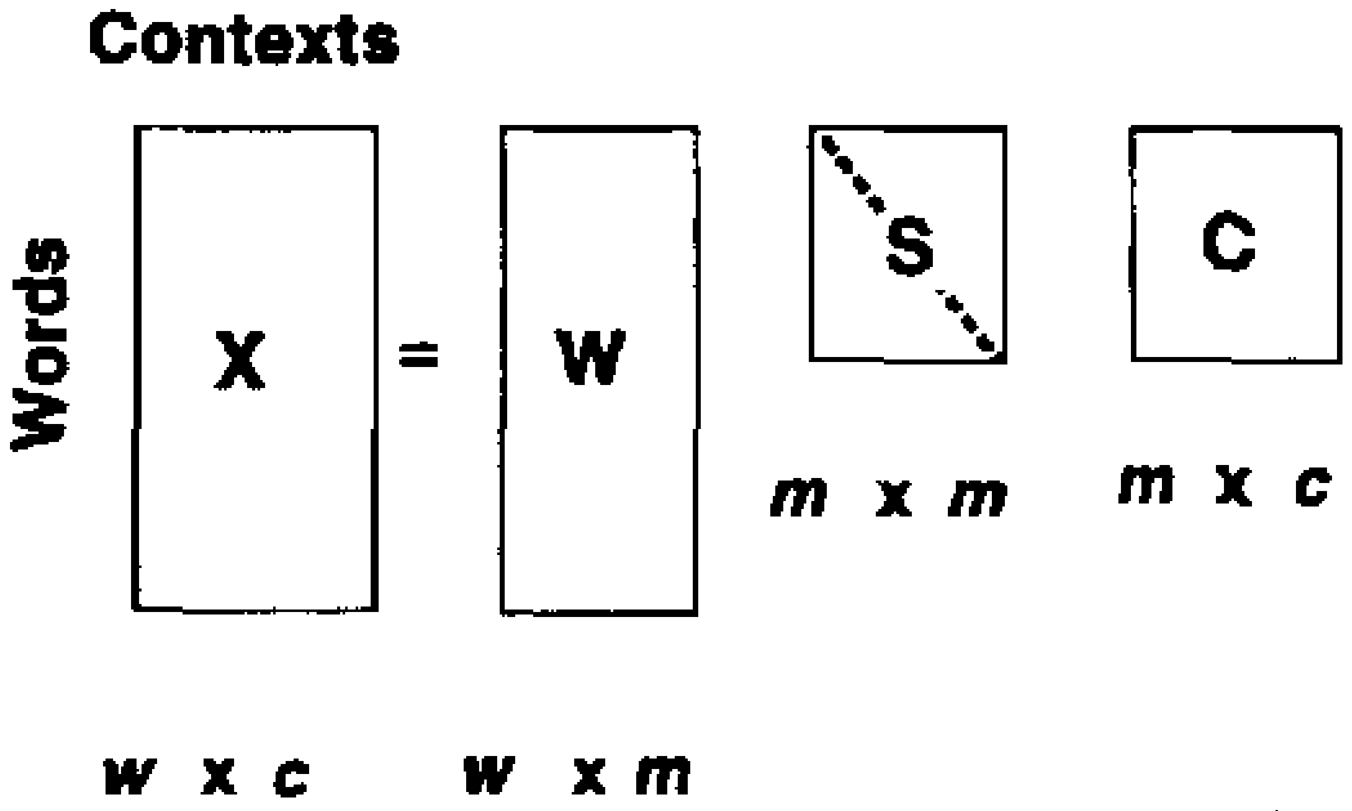
Sample Dimensionality Reduction



Sample Dimensionality Reduction



Singular Value Decomposition



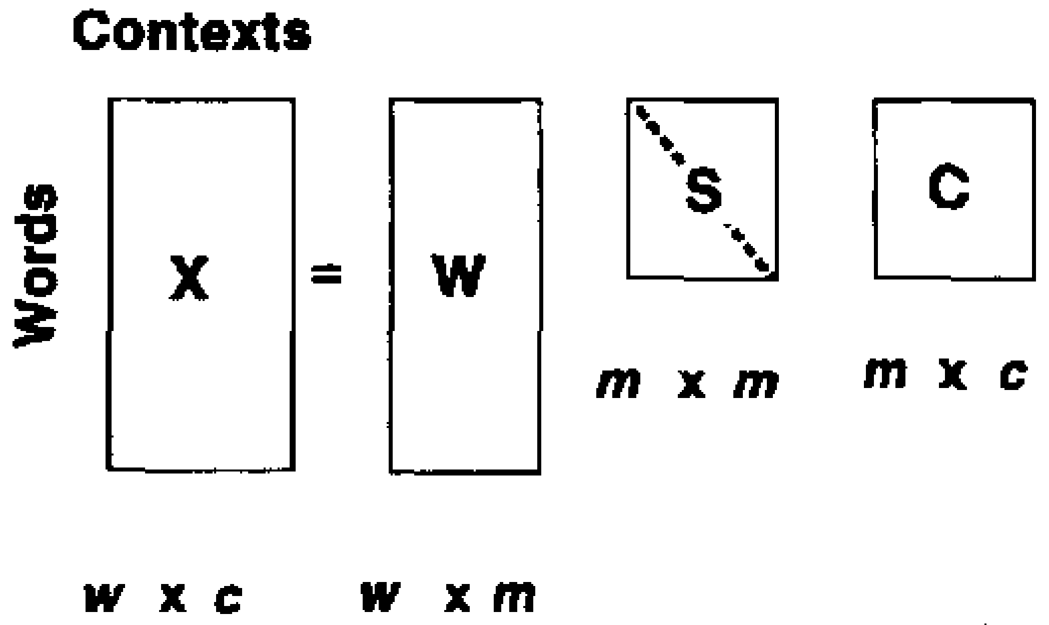
(assuming the matrix has rank m, m<c)

Singular Value Decomposition

*Any rectangular w x c matrix **X** equals the product of 3 matrices:*

W: rows corresponding to original but m columns represents a dimension in a new latent space, such that

- m column vectors are orthogonal to each other
- Columns are ordered by the amount of variance in the dataset each new dimension accounts for



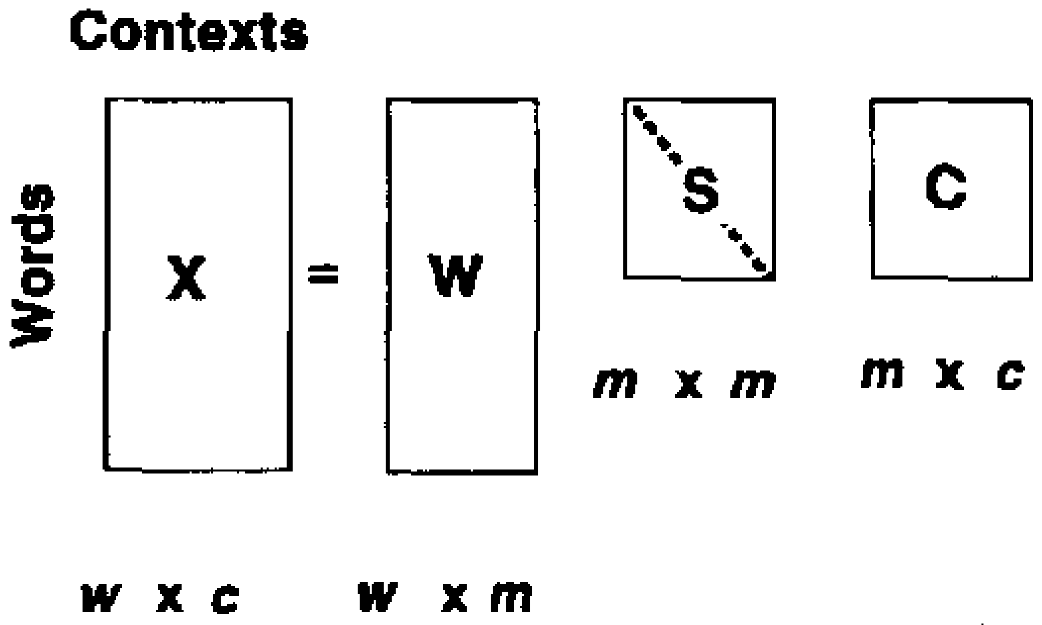
Singular Value Decomposition

*Any rectangular w x c matrix **X** equals the product of 3 matrices:*

W: rows corresponding to original but m columns represents a dimension in a new latent space, such that

- m column vectors are orthogonal to each other
- Columns are ordered by the amount of variance in the dataset each new dimension accounts for

S: diagonal *m* x *m* matrix of **singular values** expressing the importance of each dimension.



Singular Value Decomposition

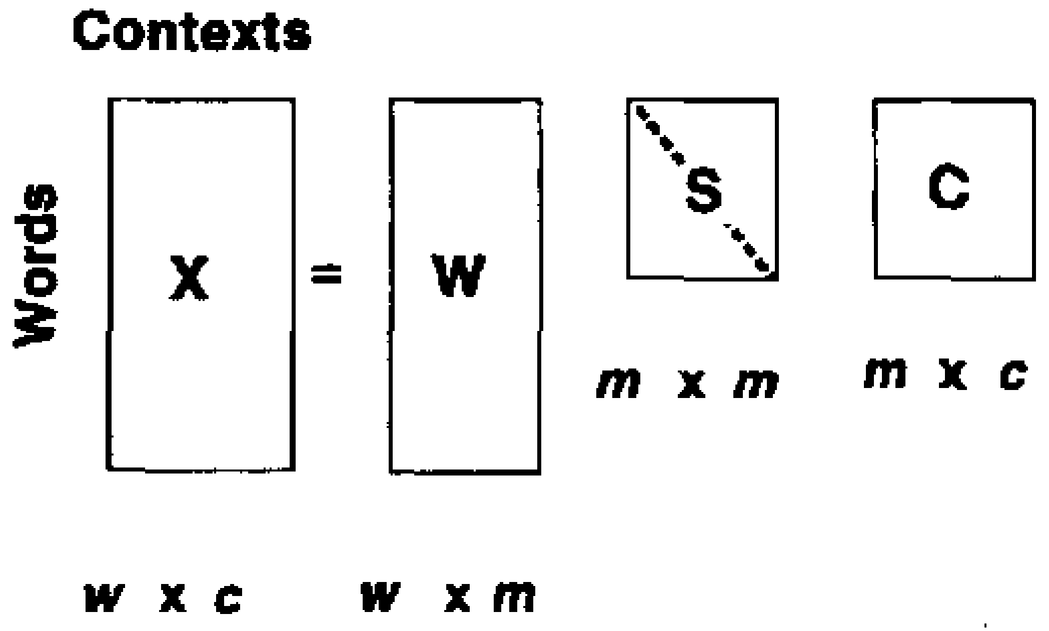
*Any rectangular w x c matrix **X** equals the product of 3 matrices:*

W: rows corresponding to original but m columns represents a dimension in a new latent space, such that

- m column vectors are orthogonal to each other
- Columns are ordered by the amount of variance in the dataset each new dimension accounts for

S: diagonal *m* x *m* matrix of **singular values** expressing the importance of each dimension.

C: columns corresponding to original but m rows corresponding to singular values



Singular Value Decomposition

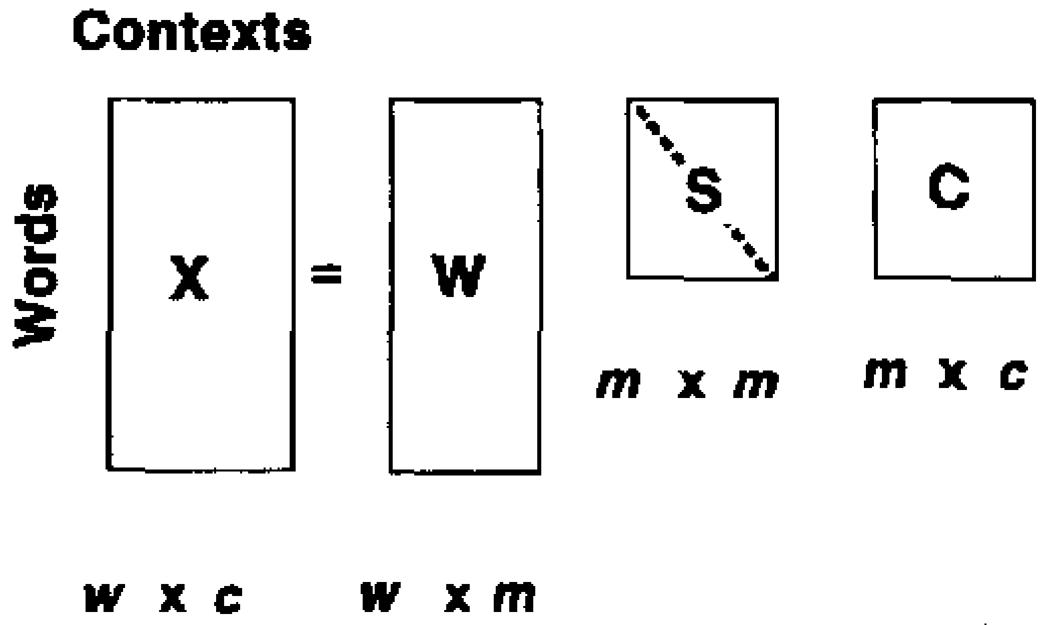
Any rectangular w x c matrix ***X*** *equals the product of 3 matrices:*

W: rows corresponding to original but m columns represents a dimension in a new latent space, such that

- m column vectors are orthogonal to each other
- Columns are ordered by the amount of variance in the dataset each new dimension accounts for

S: diagonal *m* x *m* matrix of **singular values** expressing the importance of each dimension.

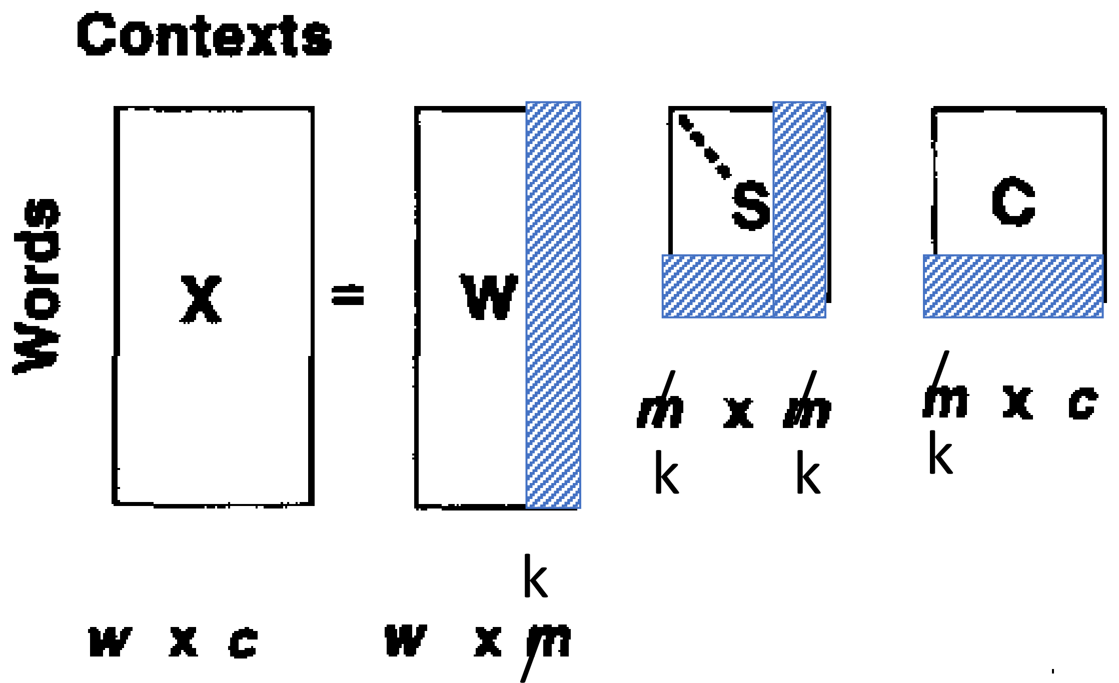
C: columns corresponding to original but m rows corresponding to singular values



Existing tools from Python, MATLAB, R, etc, for SVD

SVD applied to word-document matrix

- If instead of keeping all m dimensions, we just keep the top k singular values. Let's say 300.
- Each row of W (keeping k columns of the original W):
  - A k-dimensional vector
  - Representing word w



SVD on Word-Document Matrix: Example

- The matrix X

	d_1	d_2	d_3	d_4	d_5	d_6

More details

- 300 dimensions are commonly used
- The cells are commonly weighted by a product of two weights (TF-IDF)
    - Local weight: term frequency (or log version)
    - Global weight: idf

Let’s return to PPMI word-word matrices

- Can we apply SVD to them?

SVD applied to term-term matrix

$$\underset{|V|\times|V|}{\begin{bmatrix} \\ \\ X \\ \\ \\ \end{bmatrix}} = \underset{|V|\times|V|}{\begin{bmatrix} \\ \\ W \\ \\ \\ \end{bmatrix}} \underset{|V|\times|V|}{\begin{bmatrix} \sigma_1 & 0 & 0 & \dots & 0 \\ 0 & \sigma_2 & 0 & \dots & 0 \\ 0 & 0 & \sigma_3 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & \sigma_V \end{bmatrix}} \underset{|V|\times|V|}{\begin{bmatrix} \\ \\ C \\ \\ \\ \end{bmatrix}}$$

(assuming the matrix has rank |V|, may not be true)

SVD applied to term-term matrix

$$\underbrace{\begin{bmatrix} \\ \\ X \\ \\ \\ \end{bmatrix}}_{|V| \times |V|} = \underbrace{\begin{bmatrix} \\ \\ W \\ \\ \\ \end{bmatrix}}_{|V| \times |V|} \underbrace{\begin{bmatrix} \sigma_1 & 0 & 0 & \dots & 0 \\ 0 & \sigma_2 & 0 & \dots & 0 \\ 0 & 0 & \sigma_3 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & \sigma_V \end{bmatrix}}_{|V| \times |V|} \underbrace{\begin{bmatrix} \\ \\ C \\ \\ \\ \end{bmatrix}}_{|V| \times |V|}$$

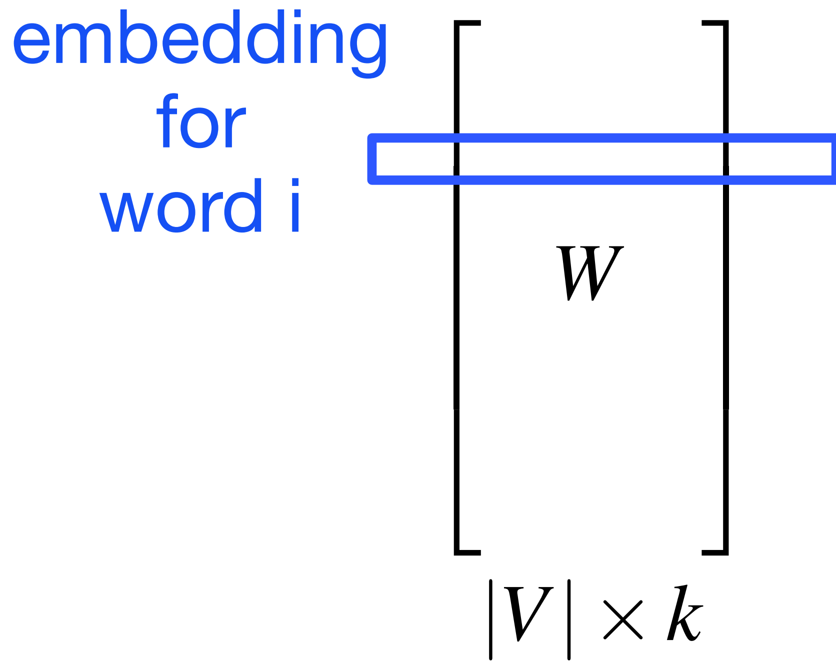
(assuming the matrix has rank |V|, may not be true)

Truncated SVD on term-term matrix

$$\underset{|V| \times |V|}{\begin{bmatrix} \\ \\ & X & \\ \\ \\ \end{bmatrix}} = \underset{|V| \times k}{\begin{bmatrix} \\ \\ & W & \\ \\ \\ \end{bmatrix}} \underset{k \times k}{\begin{bmatrix} \sigma_1 & 0 & 0 & \dots & 0 \\ 0 & \sigma_2 & 0 & \dots & 0 \\ 0 & 0 & \sigma_3 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & \sigma_k \end{bmatrix}} \underset{k \times |V|}{\begin{bmatrix} & C & \end{bmatrix}}$$

Truncated SVD produces embeddings

- Each row of W matrix is a k-dimensional representation of each word *w*
- k might range from 50 to 1000
- Generally we keep the top k dimensions, but some experiments suggest that getting rid of the top 1 dimension or even the top 50 dimensions is helpful (Lapesa and Evert 2014).



Embeddings versus sparse vectors

- Dense SVD embeddings sometimes work better than sparse PPMI matrices at tasks like word similarity
  - Denoising: low-order dimensions may represent unimportant information
  - Truncation may help the models generalize better to unseen data.
  - Having a smaller number of dimensions may make it easier for classifiers to properly weight the dimensions for the task.
  - Dense models may do better at capturing higher order co-occurrence.
